

**TAXONOMIC STUDIES AND THE EVOLUTION OF HABITAT  
PREFERENCE IN THE CYSTOBASIDIOMYCETES**

by

**Pedro Pablo Parra Giraldo**

**A Dissertation**

*Submitted to the Faculty of Purdue University*

*In Partial Fulfillment of the Requirements for the degree of*

**Doctor of Philosophy**

Department of Botany & Plant Pathology

West Lafayette, Indiana

August 2019

**THE PURDUE UNIVERSITY GRADUATE SCHOOL**  
**STATEMENT OF COMMITTEE APPROVAL**

Dr. Mary Catherine Aime, Chair

Department of Botany and Plant Pathology

Dr. Jin-Rong Xu

Department of Botany and Plant Pathology

Dr. Stephen Goodwin

Department of Botany and Plant Pathology

Dr. Michael Gribskov

Department of Biological Sciences

**Approved by:**

Dr. Christopher J. Staiger

Head of the Graduate Program

*To my mother for her tenacity and faith.*

*To my father for teaching me the value of honesty and humbleness*

*To Juanita, Mariangel and Carolina for being my motivation to never give up*

*To Rato for loving me and teaching me so much. For making out of me a better man*

## ACKNOWLEDGMENTS

Thank you Dr. Aime for your support, for giving me a life lesson and showing me the path to follow. Thanks to the members of my academic committee: Dr. Xu, Dr. Gribskov and Dr. Goodwin for your guidance and suggestions. Thanks to Dr. Mengiste for being a great prelim chair.

Special thanks to Dr. Goldsbrough and Dr. Staiger for your unrestricted support and your guidance. Thanks to you my dear friend Jorge for opening the doors of your house since day one. Thank you for your support, for your advice and encouragement, for always being willing to discuss and provide accurate and useful input. Thanks to all the Aime Lab, great current and past members (if I mention all of them it would be a whole chapter of this dissertation) for putting a piece of your knowledge and life into mine. Thank you, John Cavaletto, for showing me how a passionate teacher should look like, for your cooperation and guidance. Thank you, Katherine Rivera, for your support, for being such a good listener, for always being there, for your happiness and laughter. Thanks, *Rapu* for all the happy moments, for the amazing years, for your love. Thanks to Rodrigo Rodriguez, for always being available to listen to me, to my stories and for showing me a different way to understand life. Hansel, thank you for your advice and helping me keep on track. Thanks to Eliana, for the good moments. Thanks to Vanessa, best roommate ever. Thank you, Lisa, Pam, Stacey for being so helpful and nice. Thanks to Dr. Morris Levy and Maria Levy for trusting in me and being so supportive along these years. Thanks to Dr. Bernhard and Dr. Alonso for teaching me the love for Science. To my friends in Colombia, David, Jesus, German and Nodier. Thanks to Hector, I still remember those words. Thanks to all of my friends that I may forget to mention in this paragraph. I am thankful for having all of you in my life.

Title: Taxonomic Studies and Evolution of Habitat Preference in the Cystobasidiomycetes.

Committee Chair: M. Catherine Aime

Pucciniomycotina is a subphylum with a high diversity in terms of habitat and life history strategies that include plant parasites, animal associates (including opportunistic human pathogens), saprobes and antagonists of other fungi. The class Cystobasidiomycetes within this subphylum is a representative of such diversity and remains understudied. Their role in nature and the associations they establish with their hosts for most of the species is still unknown. In this study we used taxonomic and phylogenetic methods to present an inventory of strains in this class collected for more than 20 years from all over the world and preserved in the Aime Lab Culture Collection. Molecular and morphological data for six new species in the genera *Bannoa*, *Buckleyzyma*, *Halobasidium* and *Sakaguchia* were also presented. Additionally, mating experiments were performed by pairing strains of *Bannoa*; this is the second time in the genus that clamp connections and basidia are observed. We also found that newly described species of *Bannoa* can be co-inhabitants of sori of rust fungi. In general, antagonistic interactions can occur through: 1) direct physical contact between two fungi, i.e., mycoparasitism; or, 2) the production of antimicrobial compounds. In the Cystobasidiomycetes, direct physical antagonistic interaction which is associated with sexual states has been reported in species of *Cystobasidium*, *Naohidea*, *Cyphobasidium* and *Occultifur*. On the other hand, the production of antimicrobial compounds which mainly occurs between the yeast stage of the fungi and other organisms has only been reported in *Cystobasidium pallidum* and *Hasegawazyma lactosa*. We also hypothesize that the common ancestor to Cystobasidiomycetes is a mycoparasite due to the fact that this life strategy is present in most of the lineages in the class. To test this hypothesis, we grouped into five categories the host association or substrate from which strains of extant species in the Cystobasidiomycetes were isolated, i.e., animals, plants, fungi, aquatic or decaying organic matter. We constructed a resolved phylogeny for the class based on seven loci to study the evolutionary origins of mycoparasitism through ancestral character reconstruction with representation of all

described species. Our analysis suggests that the most likely hypothesis is that the most recent common ancestor of the Cystobasidiomycetes was associated to fungi.

## CHAPTER 1. A LITERATURE REVIEW OF THE CYSTOBASIDIOMYCETES

Pucciniomycotina comprises more than 8400 described species, i.e., more than 8% of described fungi (Kirk et al 2008) and is the sister group to Ustilaginomycotina and Agaricomycotina (Aime et al. 2014). Some species of Pucciniomycotina are known to cause some of the most devastating diseases of crops (e.g., the rust of coffee *Hemileia vastatrix*) as well as causing rare infections in humans (*Cystobasidium minutum* has been reported causing unusual infection in hip-joint prosthesis) (Cutrona et al. 2002), while others have shown potential as biological control organisms of invasive plants and other pathogenic fungi (Evans 1993, Lutz et al. 2004) or can be found asymptotically in the phylloplane. Circa 90% of the known species in Pucciniomycotina belong to a single order, the Pucciniales or the rust fungi (Kirk et al 2008) in the Pucciniomycetes: the other fungi in the subphylum classified in the eight remaining classes, are very diverse in terms of their ecology, physiology and biology (Aime et al. 2006, Aime et al. 2014). Among the classes in Pucciniomycotina, in which a high diversity in ecology and biology has been documented are the Cystobasidiomycetes.

The Cystobasidiomycetes (Basidiomycota: Pucciniomycotina) proposed by Bauer et al. (2006), is a class in which the majority of species are pink, orange-red or salmon-colored dimorphic or unicellular yeasts. Higher-level classification studies using molecular data of the 18S and 28S ribosomal RNA genes (Aime et al. 2006, Bauer et al. 2006) resolved three orders, Cystobasidiales, Erythrobasidiales and Naohidiales. In 2015, Wang and collaborators, conducted phylogenetic studies using seven genes, including nuclear ribosomal genes and protein-coding genes namely, 18S, ITS, 28S, *rpb1* (RNA polymerase II subunit *rpb1*), *rpb2* (RNA polymerase II subunit *rpb2*), *tef1* (translation elongation factor EF-1 alpha) and the *cytb* (Cytochrome b). Protein-coding gene sequences had not been extensively used in phylogenetic studies on Basidiomycetous yeast (Wang et al. 2015a) and were used to robustly reassess the boundaries of genera in several classes of Pucciniomycotina including the Cystobasidiomycetes.

In that study, it was also possible to accommodate species belonging to the anamorphic genera *Rhodotorula* and *Sporobolomyces* in several genera such as *Bannoa*, *Erythrobasidium* and *Hasegawazyma* in the Erythrobasidiales and in *Cystobasidium* in the Cystobasidiales. In the same study, two genera, *Buckleyzyma* and *Microsporomyces*, were erected to accommodate species

belonging to the former aurantiaca and magnisporus group, respectively (Wang et al. 2015a). In 2016 Spribille and collaborators, identified a new lineage of lichen-inhabitant yeast that were later included within *Cyphobasidium*, erected by Millanes et al. (2016). Subsequently, in 2017 the orders Buckleyzymales and Sakaguchiales were proposed to accommodate species in *Buckleyzyma* and *Sakaguchia*, respectively (Zhao et al. 2017). Currently, the Cystobasidiomycetes consists of 13 genera and over 70 species placed in five orders: Buckleyzymales, Cystobasidiales, Erythrobasidiales, Naohideales and Sakaguchiales (Aime et al. 2006, Bauer et al. 2006, Spribille et al. 2016, Zhao et al. 2017).

Species belonging to the Cystobasidiomycetes have been isolated from different habitats, ranging from aquatic environments, soil, insects, mammals and plants either as endophytes or living on the surface of leaves. Several other species have been found in association or antagonizing other fungi. Mycoparasitism is one of the several antagonistic interactions observed in fungi and consists in the direct physical contact between two fungi and has been reported in some genera within the class namely *Cystobasidium*, *Naohidea*, *Cyphobasidium* and *Occultifur*. On the other hand, antagonism can also occur through the production of toxic compounds and other agents against competing organisms, through the competition for nutrients or by stimulating host defense mechanisms (Karlsson et al. 2015, Narayanasamy 2013). These two phenomena have been reported in the Cystobasidiomycetes only on *Cystobasidium pallidum* and *Hasegawazyma lactosa*. These antagonistic interactions as well as the mechanism that fungi have developed to defend (such as the production of biofilms) from competing organisms has not been compiled for all species in the Cystobasidiomycetes. Considering this, we included in this chapter information collected from the literature and data generated in our lab regarding the formation of a ring when strains are incubated in liquid media (Figure 1.2). This ring can be interpreted as a biofilm (See chapter 5).

#### 1.1.1 *Naohidea*

This monotypic genus is found in an early-diverging lineage within the Cystobasidiomycetes. In nature, hyphae are thin-walled, clamped mycelia are observed and long basidia without a probasidium with four short sterigmata are present (McNabb 1965). In the hyphal stage, *Naohidea sebacea* is parasitic on fructifications of other fungi and interacts with its host through intracellular haustoria (Bauer et al. 2006). *Naohidea sebacea* does not produce either orange, red or pink

pigmented colonies, instead, it produces cream-colored or beige to pale yellowish colonies in culture (Sampaio and Chen, 2011). Yeast cells occur singly or in parent-bud pairs, pseudohyphae is absent. Because of the position of *Naohidea* within the Cystobasidiomycetes, it is suggested that the Cystobasidiomycetes may have arisen from nanometer-fusion (i.e., small channel-like structures used to parasitize host cells) mycoparasites (Bauer et al 2004, Bauer et al 2006). *Naohidea sebacea* has been mainly found on old stromata of *Botryosphaeria dothidea* (Piatek 2002), *Botryodiplodia* sp., *Botryosphaeria quercuum* (Mcnabb 1965), on a sphaeriaceous fungus (Olive 1947) and on pycnidia of a *Phialophorophoma*-like fungus (Bandoni 1973). However, *N. sebacea* also has been isolated from *Fraxinus* sp. and maple (Berk and Broome 1971).

### 1.1.2 *Cystobasidium*

The genus *Cystobasidium* comprises 20 species, some of them dimorphic. The hyphal septal pore is simple and is occluded by a cystosome, which is a cylindrical structure with a reticulate surface (Sampaio and Franz Oberwinkler 2011). The hyphal stage of *Cystobasidium fimetarium*, the type species of the genus, has been found growing on dung with other ascomycetous fungi such as *Thelebolus crustaceus* and *Lasiobolus equinus* on which it is presumed to be mycoparasitic (Roberts 1999). An asexual stage has not been documented either in nature or laboratory conditions. Other species have been found in association with other fungi during the hyphal stage. For example, *C. sebaceum* was found growing on remnants of an old *Sebacina* sp. on decaying wood (Martin 1939). Also, *C. proliferans* has been found growing on excreta on the inner surface of bark of dead pines (Olive 1952). Out of the three species in which a hyphal stage has been observed, *C. sebaceum* and *C. proliferans* lack molecular data because of it, their phylogenetic affiliation is still unclear. The remaining species have been described from their sexual stage, exhibiting ovoid to elongate cells, occurring singly or in pairs, budding is predominantly polar and colony color ranges from pink to orange or red (Figure 1D, 1E). According to Sampaio and Oberwinkler (2011), species in this genus do not produce ballistoconidia. Species in the genus, may or may not produce a pellicle, ring or sediment when cultured in liquid media. Ring production is observed in *Cystobasidium calyptogenae*, *C. laryngis*, *C. lysinophilum*, *C. minutum*, *C. pinicola*, *C. portillonense*, *C. slooffiae*, and *C. ongulense*. Ring formation has not been observed in *Cystobasidium oligophagum* or *C. benthicum*. Species in *Cystobasidium* have been isolated from

a great variety of habitats and substrates ranging from tropical to Antarctic regions and from marine habitats to plants.

### 1.1.3 *Occultifur*

*Occultifur* comprises ten species some, of which are dimorphic, with *O. internus* as the type species for the genus. This fungus is a presumed mycoparasite that interacts with its Dacrymycetales host through haustorial cells (Olive 1954, Bauer et al. 2006). An asexual stage has not been reported either in nature or under laboratory conditions for this species. Other species in *Occultifur* in which the hyphal stage has been observed are *O. corticorum*, isolated from a basidiocarp of *Tylospora fibrillosa* (Roberts 1997), *O. externus* isolated from plant litter and sea water (Sampaio et al. 2013), *O. lumbricifer*; described as an intrahymenial parasite on *Hyphodontia subalutacea* (Roberts 2001), *O. kilbournensis*, isolated in its asexual stage from overwintered maize stalks and for which a hyphal stage was observed under laboratory conditions after being paired with other compatible strains (Kurtzman and Robnett 2015), and *O. rivoirei* isolated from *Hyphodontia arguta* (Trichies 2016). Other species such as *O. brasiliensis*, *O. mephitis*, *O. tropicalis* and *O. plantarum* are known only from their asexual stage in which true hyphae or pseudo hyphae are not formed (Gomes et al. 2015, Khunnamwong et al. 2015, Kurtzman and Robnett 2015). In the asexual stage, cells occur singly or in parent-bud pairs and budding is mainly polar. *Occultifur brasiliensis* produces white colonies initially (days 1-3) and then colonies turn light pink. Production of a ring or pellicle has not been investigated in the genus.

### 1.1.4 *Erythrobasidium*

*Erythrobasidium*, with *E. hasegawianum* as the type species, is a small genus that comprises only three species. The type strain was isolated from an old culture of beer yeast. Under laboratory conditions, *E. hasegawianum*, produces uninucleate mycelia directly from a single cell without mating after 10 days on corn meal agar (CMA, Difco) at 25 C, dikaryotic hyphae were observed when clamp connections were present. After 50-60 days, protrusions emerged laterally from the hyphae to produce a basidium with four terminal basidiospores (Hamamoto et al. 1988). Development of hyphae, clamp connections and sexual structures from a single cell has never been reported in other species in the class. Previous studies such as those conducted on *O. externus* and *O. kilbournensis* in which a hyphal stage was developed, always involved mating between two

compatible strains (Sampaio et al. 2013, Kurtzman and Robnett 2015). However, when we tried to replicate the results obtained by Hamamoto et al. 1988, using the same strain (CBS 8253 = ATCC 9536), media and under the same growing conditions, we were unable to induce the formation of hyphae or any of the structures reported. The genome of *E. hasegawianum* is presumably diploid. If that is the case, it would be the only known member of the Cystobasidiomycetes in which sexual structures are developed from a diploid cell. In other species in the genus, a hyphal stage and sexual structures have not been observed. During the asexual stage, species in *Erythrobasidium* produce orange to red pigmented colonies (Figure 1B, 1C), yeast cells occur in single or in parent-bud pairs. Budding can be lateral or multilateral. Ballistospores have been reported in *E. elongatum* and *E. yunnanense* but not in *E. hasegawianum*. Pseudohyphae are present only in *E. elongatum*. A ring and pellicle are produced in all the species when cultured in liquid media. Species in the genus have been isolated from plants, mangrove sediments, fresh and seawater (Shivas and Rodrigues de Miranda 1983, Bai et al. 2001, Chanprasartsuk et al. 2013, Gomes et al. 2015).

#### 1.1.5 *Bannoa*

The genus *Bannoa* comprises seven species with some being dimorphic such as *B. hahajimensis*, the type species, in which a hyphal stage has been observed (Hamamoto et al. 2002) and *Bannoa tropicalis* sp. nov. Mycelium and clamp connections were observed after pairing of compatible strains. Obovoid basidia-like structures clamped at the base emerging laterally from the hyphae were formed (Hamamoto et al. 2002, Chapter 2). Development of sexual structures has only been observed under laboratory conditions. The asexual stage is characterized by pink to orange or red colonies (Figure 1H). Cells occur singly or in parent-bud pairs and pseudohyphae have not been reported in the genus. Ballistoconidia are produced. (Hamamoto et al. 2002, Chapter 2). When cultured in liquid media a ring is formed in *B. syzygii* and *B. ogasawarensis* but no pellicle. On the other hand, a pellicle is formed in *B. bischofia* and *B. hahajimensis*. Species in *Bannoa* have been isolated from the phylloplane, dead leaves of various plant species, rust-infected leaves and cloud water (Chiang et al. 2001, Hamamoto et al. 2002, Matheny et al. 2006, V $\ddot{a}$ tilingom et al. 2012, James et al. 2016, Raghavendra et al. 2017). *Bannoa* was traditionally known from subtropical regions, however, in recent years it has been found in the tropics, in countries such as Guyana, Mexico, Puerto Rico and Panama (Matheny et al. 2006, James et al. 2016, Chapter 2).

### 1.1.6 *Cyrenella*

*Cyrenella elegans* is the only species in this genus. A hyphal stage with clamp connections and spherical teliospores constitutes the sexual stage. Conidia that emerge from dikaryotic hyphae are thin-walled with three to four apical appendages (Gochenaour 1981). They are referred to as tetraradiate conidia and are presumed to be an adaptation to aquatic environments (Gochenaour 1981, Sampaio 2011). In culture, colony color is orange, cells are ovoid to elongate and occur singly or in parent-bud pairs. Budding is predominantly polar, but sometimes multilateral. Ballistoconidia are not formed. Formation of a ring or pellicle in culture conditions have not been observed. *Cyrenella elegans* has been isolated from sand scraped from a submerged stipe of *Laccaria trullisata* (Gochenaour 1981, Sampaio 2011).

### 1.1.7 *Hasegawazyma*

The only species in the genus is *Hasegawazyma lactosa*. Its sexual stage is unknown. Colonies in media are pink. The asexual stage is characterized by ellipsoid to ovoid yeast cells, occurring singly or in parent-bud pairs, budding is predominantly polar and pseudohyphae are not produced. Ballistospores have not been observed (Hasagawa 1959). After one month in liquid media we were able to see formation of a ring, and a pellicle was formed on the surface when the type strain was cultured in liquid media. *Hasegawazyma lactosa* was isolated from air sampling in cowsheds but also has been isolated from mangrove sediments and sea water (Hasagawa 1959, Sampaio 2011).

### 1.1.8 *Cyphobasidium*

Until recent years, the phylogenetic position of lichen-inhabiting taxa within Pucciniomycotina such as *Chionosphaera* and *Cystobasidium* (Diederich 2007) was uncertain due to the lack of molecular data. For that reason, lichenicolous fungi in the Cystobasidiomycetes were placed in *Cystobasidium* based merely on morphological characters (Diederich 1996) and only after molecular data became available was possible to establish their real position within the class. *Cyphobasidium* was erected to accommodate *Cyphobasidium usneicola* and *Cyph. hypogymniicola* (Millanes et al. 2016). The genus is characterized by producing galls on the lichen thalli, also species in the genus are the only representatives in the Cystobasidiomycetes in which the hyphal stage (sexual stage) is predominant in nature (Millanes et al. 2016). Contrarily, Spribille et al (2016) suggest that the filamentous stage is rarely observed. The presence of a sexual stage

within the galls suggests that species in the genus complete their life cycle within the lichens (Spribille et al. 2016). On *Hypogymnia physodes*, the species *Cyph. hypogymniicola* induces the formation of galls, the hypha is present but clamp connections and haustorial branches are not observed. Basidia develop from a thick-walled probasidium and basidiospores are ellipsoid to fusiform, more or less symmetrical (Diederich 2007). The asexual stage consists of budding yeasts with round and thin-walled cells embedded in the upper cortex of the lichen (Spribille et al. 2016). *Cyphobasidium hypogymniicola* has been observed on *H. physodes* and *Cavernularia hultenii* while *Cyph. usneicola* was first reported from several species of *Usnea* including *U. subfloridana* (Diederich 1996, 2007, Millanes et al. 2015). Other sequences belonging to *Cyphobasidium* have been obtained from *Bryoria fremontii* and *B. tortuosa* that are nomenclatural synonyms and are recognized by the production of vulpinic acid. It was hypothesized that differential gene expression was responsible for the increased production of *B. tortuosa* in respect to *B. fremontii*. Based on the results obtained by Spribille et al. (2016), both the transcript abundance data and the abundance of cells in thalli, suggested that the higher production of vulpinic acid in *B. tortuosa* implicates *Cyphobasidium* either through the direct production or by inducing the production by the lecanoromycete.

Even though most of the sequences derived from lichens form a monophyletic clade with *Cyphobasidium*, there is a clade that appears closely related to *Microsporomyces* and *Sakaguchia* (Spribille et al. 2016) meaning, that there is at least another lichen-inhabitant evolutionary lineage within the Cystobasidiomycetes. The finding of related basidiomycetes in 52 lichen genera most of them in the Parmeliaceae from six continents, has changed the traditional definition of the lichen symbiosis and its nature in which only one fungus and a photosynthesizing symbiont is sometimes accompanied by a second photosynthesizing symbiont (Spribille et al. 2016, Hawksworth 1988)

#### 1.1.9 *Symmetrospora*

*Symmetrospora* consists of seven species with *S. gracilis* as the type species. A sexual state has not been reported in any species of the genus. The asexual stage produces orange to red colonies (Figure 1I); cells occur singly or in parent-bud pairs. Symmetrical ballistospores are produced in all species. When cultured in liquid media, the production of a ring has been reported in *S. coprosmae*, *S. marina*, *S. oryzicola* and *S. vermiculata*, while a pellicle on the surface of liquid media has been observed in *S. coprosmae*, *S. folicola* and *S. vermiculata*. Species in the genus have

been isolated from the phylloplane of several plant species, dead leaves, the roots of plants, mangrove sediments, the gut of *Diabrotica virgifera*, aphids (*Aphis spiraecola*), shrimps (*Peneaus setiferus*) and the fruiting body of *Pleurotus* sp. (Nakase and Suzuki 1986, Nakase and Takashima 2000, Wang and Bai 2004).

#### 1.1.10 *Buckleyzyma*

*Buckleyzyma* is a small genus in the Buckleyzymales comprising six species with *B. aurantiaca* as the type species. Rudimentary septate hyphae were observed in *B. kluyveri-nielii* while in *B. phyllomatis* these hyphae were described as adventitiously septate hyphae that delimited terminal lipid-rich cells (Van Der Walt et al 1986, 1988). In both cases, hyphae were produced in single-cell cultures on corn meal agar (CMA, Difco) (Van Der Walt et al. 1986, 1988). The clamp connections or development of sexual structures have not been observed in the genus. The asexual stage in *Buckleyzyma* species consists of pink-salmon to orange colonies (Figure 1A) with ellipsoidal to cylindrical cells that in general occur singly or in parent-bud pairs. In *B. phyllomatis*, cells sometimes appear organized in small clusters. Budding is predominantly polar. Production of ballistoconidia and pseudohyphae has been reported in *B. kluyveri-nielii*, *B. phyllomatis* and *B. salicina* while it is absent in *B. armeniaca* and *B. aurantiaca*. Formation of a ring when cultured in liquid media has been observed in *B. aurantiaca*, *B. kluyveri-nielii* and *B. phyllomatis*. Formation of a pellicle on the media has not been observed in *Buckleyzyma*. Species in *Buckleyzyma* have been isolated from the phylloplane of several plant species, from air sampling, lake water, mangrove sediments and litter (Shivas and Rodrigues de Miranda 1983, Johri and Bandoni 1984, Van Der Walt et al 1986, 1988).

#### 1.1.11 *Sakaguchia*

*Sakaguchia* contains six species, in which *S. dacryoidea* is the type. In the type, development of sexual structures and hyphae with clamp connections occur after compatible strains are paired. Two- to four-celled basidia (promycelium) germinate from a thick-walled teliospore. In the basidium, lateral and terminal haploid basidiospores are produced (Fell et al. 1973). For other species in the genus a sexual stage has not been reported. In the asexual stage, species in *Sakaguchia* exhibit pigmented colonies ranging from light pink to orange or red. Cells are arranged in parent-bud pairs (Fell et al. 1973, 2011, Wang et al. 2015b). Cell shape can be ovoidal,

ellipsoidal or cylindrical. Budding is polar or multilateral. Pseudo hyphae are not formed, however cells of *S. cladiensis* and *S. dacryoidea* can be found in short chains (Fell et al. 1973, 2011). Ring formation has only been reported in *S. oryzae*, but not the presence of a pellicle on the liquid media. Species in *Sakaguchia* have been isolated from sea water, fresh water, the gut of fish, tube worm (*Lamellibrachia* sp.), mangrove sediments, and plants such as *Oryza sativa* and *Avicennia germinans* (Fell et al. 1973, Nagahama et al. 2001, Almeida and Sampaio 2003, Libkind et al. 2003, Libkind et al. 2010, Fell et al. 2011, Velmurugan et al. 2013, Raggi et al. 2014, Francis et al. 2016).

#### 1.1.12 *Microsporomyces*

The genus comprises five species for which *Microsporomyces magnisporus* is the type. A sexual stage has not been reported in *Microsporomyces*. The asexual stage generally produces orange or salmon colonies. However, *M. hainanensis* colonies are brownish white. Cells occur singly or in parent-bud pairs, but in *M. magnisporus* cells can be found in small clusters. Budding can be either monopolar or multilateral. Ballistospores are only reported in *M. magnisporus* and pseudohyphae are observed in *M. pini*, *M. hainanensis* and *M. magnisporus*. Formation of a ring has been reported in *M. hainanensis* and *M. magnisporus* while a pellicle is not formed.

#### 1.1.13 *Halobasidium*

*Halobasidium* is a recently described monotypic genus in which *Halobasidium xiangyangense* is considered a high-salt tolerant species. A sexual stage is unknown, and its asexual stage exhibits orange to light pink colonies (Figure 1F), cells that are globose or ellipsoidal and occur singly or in parent-bud pairs. Budding is predominantly polar. Sometimes short chains of two or three buds and occasionally Y-shaped groups, but pseudohyphae have not been observed. The type strain was isolated from pickling sauce used to make Datoucai, which is a traditional fermented food made of *Brassica juncea* in China (Guo et al. 2019).

There are over 790 reports in the NCBI, either of strains or sequences of the Cystobasidiomycetes obtained from environmental studies; 378 (47.7%) of these reports have not been affiliated to any of the extant species in the class, while there are other 55 (6.9%) ambiguously classified. This means, that several sequences have been named in a species to which they do not belong. In total, over 54% of sequences included in this dissertation that were retrieved from the

NCBI have some taxonomic uncertainty for which the study of the ecology, host preference and geographic distribution remains obscure (For further detail on species delimitation and classification of sequences in the Cystobasidiomycetes see Chapter 4). However, those are not the only difficulties when studying this class. Reproductive biology of species is also understudied, just a couple of species such as *O. kilbournensis*, *O. externus* and *Bannoa hahajimensis* have been studied under laboratory conditions in this regard. In Chapter 2, we discuss the reproductive biology of a newly described *Bannoa tropicalis* making a contribution to the existing knowledge about the reproductive biology of species in the class. In addition, several species lack molecular data for which it has not been possible to establish their phylogenetic placement, for example, the affiliation of *O. internus* which is the type species for the genus remained unknown until now. We have generated molecular data that would allow to better understand phylogenetic relationships and bring more clarity to the taxonomy of the Cystobasidiomycetes.

In the present chapter, we compile available information of all the 13 genera in the class including features of the most recently described species. We make emphasis on the sexual stage of species in the class, since it is during this stage in which several antagonistic interactions have been documented in nature. Nevertheless, these interactions do not only occur through direct physical contact, i.e., mycoparasitism, but also, they can occur through the production of antimicrobial compounds. This latter phenomenon and how microorganisms defend themselves from these compounds is understudied in the Cystobasidiomycetes

## CHAPTER 2. NEW SPECIES OF *BANNOA* DESCRIBED FROM THE TROPICS AND THE FIRST REPORT OF THE GENUS IN SOUTH AMERICA

### 2.1 Abstract

The genus *Bannoa* consists of four described species associated with dead leaves in southwestern Japan. In this study we describe three new species, *Bannoa guamensis*, *B. rosea*, and *B. tropicalis*, from the South Pacific island of Guam and Guyana in South America. Isolates were obtained from surfaces of diseased and healthy leaves of plants in the Euphorbiaceae, Asteraceae, and Poaceae. DNA sequences from four gene regions including nuclear rDNA ITS1-5.8S-ITS2 (ITS), D1–D2 domains of nuclear 28S rDNA (28S), nuclear 18S rDNA (18S), and a portion of *tef1*, which encodes translation elongation factor 1- $\alpha$ , were used for phylogenetic analysis. Intercompatibility tests were performed and subsequent development of clamp connections and basidia were documented for *B. tropicalis*. Potential life history strategies and association with diseased leaves including rust-infected leaves were evaluated across the genus. This is the first report of a species of *Bannoa* from South America.

### 2.2 Introduction

*Bannoa* in the Cystobasidiomycetes was erected as a monotypic genus based on the dimorphic yeast *B. hahajimensis* (Hamamoto et al. 2002) isolated from dead leaves of *Bryophyllum pinnatum* commonly known as cathedral bells is a succulent plant from the Crassulaceae family native to Madagascar, from *Rhaphiolepis wrightiana* known as Japanese-hawthorn that belongs to the Rosaceae family and from *Syzygium buxifolium* known as the boxleaf Eugenia that belongs to the Myrtaceae family, all collected from Haha-jima island in south Japan. Based on analysis of the nuclear 18S rDNA (18S) and nuclear ITS1-5.8S-ITS2 rDNA (ITS) regions of the rDNA repeat, *B. hahajimensis* was placed in the Erythrobasidiales and remained the only recognized species for 15 years (Hamamoto et al. 2002). In 2015, *Sporobolomyces bischoffiae*, *S. ogasawarensis*, and *S. syzygii* were transferred to *Bannoa* based on a seven-gene phylogeny (Wang et al. 2015a), raising the total number of known species in *Bannoa* to four. Members of *Bannoa* are rarely isolated in pure culture. Reported *Bannoa* isolates are from dead leaves of various plant species in the

Ogasawara, Iriomote-Jima, and Yakushima islands of subtropical southwestern Japan and from the surface of leaves of *Miscanthus* and other unidentified plants in Taiwan (Chiang et al. 2001). Two other isolates of *Bannoa* have been reported in Panama (Matheny et al. 2006) and from cloud water samplings in France (Vätilingom et al. 2012) but have not been named or described. However, environmental sequences indicative of *Bannoa* have been reported from *Fagus sylvatica* (European beech) in Austria (Moll et al. 2011), in Australia from herbaceous plants such as *Mimosa pigra*, *Jatropha gossypifolia* and *Vachellia nilotica* subsp. *Indica* and trees such as *Parkinsonia aculeata* and *Tamarix aphylla*, (Raghavendra et al. 2017), and from sori of *Hemileia vastatrix* on coffee plant leaves in Mexico and Puerto Rico (James et al. 2016). Taken together this indicates a wider geographic range for the genus. All known isolates of *Bannoa*, except those of Vätilingom et al. (2012) from cloud water, have been associated from the phylloplane of dead asymptomatic or infected leaves. The study by James et al. (2016) suggests that some *Bannoa* and other species in the Cystobasidiomycetes such as *Symmetrospora oryzaicola* and *S. coprosmae* are capable of inhabiting the sori of rust fungi. However, it is not clear if these species are saprobes, endophytes, or mycoparasites. Examples of mycoparasitic species in the class include *Cystobasidium fimetarium*, *Naohidea sebacea*, and *Occultifur internus*, in which the hyphal stages have been found parasitizing other fungi (Roberts 1999, Piatek 2002, Bauer et al. 2006). The possibility that dimorphic species of *Bannoa* have a mycoparasitic life strategy during the hyphal stage should not be discarded.

During field collecting in Guyana and on Guam, numerous isolates of salmon-pigmented ballistosporic yeasts were isolated from diseased and asymptomatic leaf surfaces. Morphological, physiological, and phylogenetic analyses based on four loci indicate their placement within *Bannoa* in three previously undescribed species, described herein as *B. guamensis*, *B. rosea*, and *B. tropicalis*. Mating intercompatibility crosses were attempted among isolates, and basidium formation was induced in *B. tropicalis*. *Bannoa tropicalis* represents the first species of *Bannoa* to be recorded from South America.

## 2.3 Material and Methods

### 2.3.1 *Sample collection and storage*

Thirteen strains were obtained using a spore-drop method described by Toome et al. (2013) from rust-infected and asymptomatic leaves of live plants in the Asteraceae (*Bidens* sp.), Euphorbiaceae (*Euphorbia cyathophora*) and Poaceae (*Lepturus repens*) collected in Guam in 2012. One additional strain was obtained from an asymptomatic leaf of an unidentified herbaceous plant in Guyana in 2013 (Table 2.1 Collection information and GenBank numbers for material used in this study.). Cultures were maintained on potato dextrose agar (PDA; 39 g/L, Livonia, Michigan) slants at 4 C for short-term storage and in 40% glycerol vials at -80 C for long-term storage. Cultures of isolates MCA4612, MCA4647, and MCA4667 were preserved as dried inert cells and deposited as holotypes in the Kriebel Herbarium (PUL). Live cultures were also deposited at the Westerdijk Fungal Biodiversity Institute (CBS) and the Fungal Biodiversity Center and Agricultural Research Service (NRRL).

### 2.3.2 *Morphological characterization*

Each strain was cultured on yeast malt agar (YMA, Difco, Franklin Lakes, New Jersey), yeast malt broth (YM broth, Difco), and corn meal agar (CMA, Difco) at 25 C for seven days to study the morphology of colonies. These were characterized by form, elevation, margin, and surface. Colony color was determined from comparisons with the Online Auction Color Chart (oac). Cell morphology was examined using phase-contrast optics under an Olympus BH-2 compound microscope. Twenty individual cells from each strain were measured. Images were captured with an Olympus SC30 camera and cells measured using Olympus cells Sens Entry 1.14 software. The nuclear condition of individual cells and hyphae, where possible, were studied by staining the nucleus with Vectashield mounting medium with DAPI (Burlingame, California) and observed using epifluorescence on a Nikon Eclipse E800 microscope.

### 2.3.3 *Physiological studies*

Assimilation of carbon and nitrogen compounds in liquid media, fermentation tests, growth on high osmotic media, and growth on vitamin free media were performed according to Kurtzman et al. (2011). The ability of strains to grow on different carbon sources was assessed by using a Yeast

Identification Test Panel (Biolog Inc., Hayward, California) as performed in Kijpornyongpan and Aime (2017).

#### 2.3.4 DNA extraction, sequencing, and phylogenetic analyses

DNA extraction was performed from pure cultures grown on YMA using the Promega Wizard genomic DNA purification kit (Promega, Madison, Wisconsin). Phylogenetic placement of newly collected strains was inferred from sequences of ITS, D1–D2 domains of the nuc 28S rDNA (28S), 18S, and from a portion of *tef1*, which encodes translation elongation factor 1-alpha. Amplification and sequencing primers included ITS1F (Gardes and Bruns 1993) and ITS4 (White et al. 1990a), LR0R/LR5 (Vilgalys and Hester 1990), NS1/NS4 and NS3/NS8 (White et al. 1990a), and EF-FC/2218R (Rehner 2005). PCR programs for amplification of the ITS consisted of a denaturation step at 95 C for 5 min, followed by 35 cycles at 94 C for 30 s, annealing T at 45 C for 45 s, 72 C for 45 s, and a final extension step at 72 C for 7 min. For the 18S and 28S regions, the program consisted of a denaturation step at 94 C for 5 min., followed by 35 cycles at 94 C for 30 s, annealing T at 50 C and 58 C for 45 and 30 s for 28S and 18S, respectively, extension at 72 C for 1 min, and a final extension step at 72 C for 7 min. For amplification of *tef1*, the PCR program consisted of a denaturation step at 95 C for 2 min., starting with 9 cycles at 95 C for 1 min, annealing at 66 C for 1 min, and extension at 72 C for 1 min, followed by 35 cycles more at 95 C for 1 min, 56 C for 1 min, then 72 C for 1 min, and a final extension step at 72 C for 7 min. PCR products were separated in a 1% agarose gel and sent to GENEWIZ (South Plainfield, New Jersey) for direct sequencing. Sequences were edited in GENEIOUS 9.1.2 (Biomatters, Auckland, New Zealand).

For phylogenetic reconstructions, taxon selection of related species in the Erythrobasidiales was based on Aime et al. (2006) and Wang et al. (2015b). ITS and 28S regions from our *Bannoa* strains were used to run a BLASTN search against the NCBI GenBank database. Sequences from environmental sampling and previous studies closely related to *Bannoa* were included in our analyses. Accession numbers for sequences of collected strains of *Bannoa* and those from GenBank are provided in Table 2.1. *Microsporomyces magnisporus* and *M. orientalis* were used for outgroup purposes (Wang et al. 2015b). Sequences for each locus were aligned with MAFFT 7.222 (Kato et al. 2017) using the L-INS-I algorithm. To test the level of congruency of the loci used in this study, a Congruence Among Distance Matrices (CADM) analysis was performed to statistically test the level of congruence among independently built phylogenetic

trees with each gene (Campbell et al. 2011). The APE (Analyses of Phylogenetics and Evolution) package in R contains the CADM module to calculate the Kendall's W statistic that provides an estimate of the degree of congruence of two or more matrices on a scale between 0 (no congruence) and 1 (congruence) (Campbell et al. 2011). In studies performed by Sánchez-García et al. (2016), the value for the W statistic equal to 0.90 showed no significant incongruence among loci. In the present study we used 0.90 as reference value to determine the acceptable level of congruence among the loci used for describing new species in *Bannoa*.

Alignments of the 18S, ITS and 28S in a first dataset and alignments of the 18S, ITS, 28S and *tefl* in a second dataset were concatenated using GENEIOUS 9.1.2 for phylogenetic reconstruction. Ambiguously aligned regions, including *tefl* introns, were removed with GBLOCKS using the less stringent selection option (Talavera and Castresana 2007). The 4-gene concatenated alignment was uploaded to TreeBASE (study no. 23244). The GTR GAMMA-I model was selected as the substitution model for the 3 and 4-gene region alignment according to PARTITIONFINDER2 based on the Akaike Information Criterion (AIC). The protein coding gene (*tefl*) was partitioned by each codon position. Phylogenetic reconstruction was performed using Maximum Likelihood (ML) followed by 1000 bootstrap replicates using GENEIOUS 9.1.2. Bootstrap proportions (BP) are reported below. Bayesian inference (BI) was performed using MRBAYES 3.2.6 (Huelsenbeck and Ronquist 2012) with a GTR model, nts:6, rates=invgamma according and five million generations. The first 25% of trees were discarded as Burn-in.

### 2.3.5 *Mating intercompatibility*

Single-cell cultures were obtained by serial dilution. Mating experiments were performed according to Yarrow (1998) by pairing ten out of the 13 collected isolates in all possible combinations on CMA . Plates were placed under different growing conditions: Incubation at 25 C under 12:12h light:darkness, incubation at 30 C under 12:12h light:darkness conditions, and incubation at 25 C under complete darkness. Plates were monitored for 12 weeks. Development of mycelium, clamp connections, and basidia were first assessed using an Olympus SZ61 dissecting microscope. If sexual structures were present, then mountings were prepared for further observation under a compound microscope at higher magnification.

## 2.4 Results

### 2.4.1 Phylogenetic analyses

The 3- and 4-gene combined datasets comprised 2448 and 3222 nucleotide sites. Of these the ITS contributed 504 sites, 28S 557 sites, 18S 1387 sites, and *tefl* 774 sites after exclusion of introns and ambiguously aligned positions. The CADM analysis showed no significant incongruence between the four loci used in the phylogenetic studies ( $w = 0.91$ ;  $p < 0.001$ ). The 3-gene region phylogenetic tree (Figure 2.1 and the 4-gene phylogenetic reconstruction (**Error! Reference source not found.**for *Bannoa* including sequences from tropical isolates formed a monophyletic group with strong support in both Maximum Likelihood (ML) and Bayesian (BI) analysis. The overall topologies of the phylogenetic reconstruction using both 3- and 4-gene regions were similar. At least nine species-level lineages are delineated, three of which are new: *Bannoa guamensis*, *B. rosea* and *B. tropicalis*. *Bannoa rosea* isolated from asymptomatic leaves, is known only from sequences of a single strain collection and appears as an independent evolutionary lineage (BP:68 and PP:1); its sister species *B. ogasawarensis* has only been reported from dead leaves; *B. guamensis* also known from single strain collections was isolated from diseased leaves of *Bidens* sp. and appears phylogenetically related to an unclassified *Bannoa* isolated from rust-infected leaves of coffee (BP:67 and PP:0.75). Lastly, strains associated with asymptomatic leaves reported from Panama (MP3490) (Matheny et al. 2006) as *Bannoa* sp. and Thailand (TY-144, TY-177, TY-201, TY-261, TY-270 and TY-288) previously classified as *Sporobolomyces* sp. (Nakase et al. 2001) are conspecific with *B. tropicalis* (BP:59 and PP:0.80).

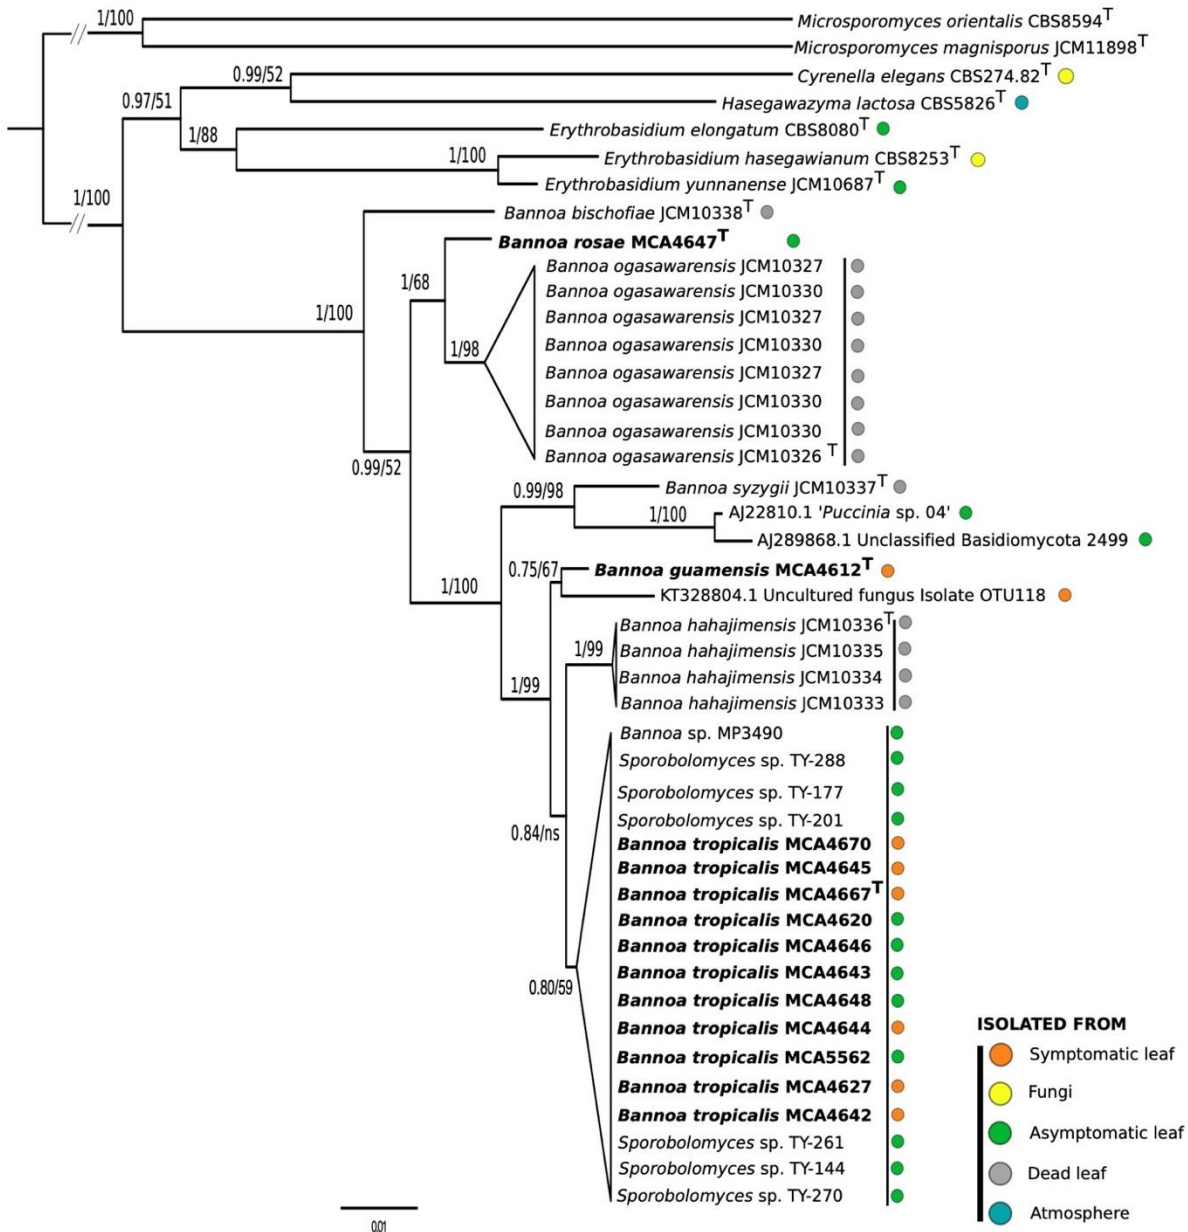

Figure 2.1 Phylogenetic reconstruction for *Bannoa* inferred from combined sequences of ITS, D1–D2 domains of nuclear 28S and nuclear 18S rDNA and *tef1* using ML and BI analysis. New species are indicated in bold. Posterior probability (PP > 0.7) and bootstrap support (BP > 50%) values are shown above nodes. ns: not supported. Tree is midpoint rooted. Scale bar equals expected number of substitutions per site. Strain number is listed in front of the taxon name. <sup>T</sup> denotes type species strain. Legend indicates substrate from which each strain was isolated.

Table 2.1 Collection information and GenBank numbers for material used in this study.

#### 2.4.2 Physiological tests

The assimilation of carbon compounds such as lactose and methanol is positive (delayed) for *B. guamensis* but negative for *B. tropicalis* and *B. hahajimensis*. Assimilation of L-sorbose is negative for *B. guamensis* while positive for *B. hahajimensis* but weak in *B. tropicalis*. Assimilation of citrate, salicin, D-arabinose and succinate is negative in *B. rosea* but positive in *B. ogasawarensis*. Nitrogen compounds such as nitrite ( $\text{NaNO}_2$ ), cadaverine, and creatinine are weakly assimilated by *B. tropicalis* but not assimilated by *B. guamensis*, *B. rosea*, or any other previously described species in the genus (Table 2.2). In addition, we found that *B. guamensis*, *B. rosea*, and *B. tropicalis* grew on vitamin-free media whereas previously described species did not (Hamamoto et al. 2002).

Table 2.2 Assimilation of carbon and nitrogen compounds and growth under different temperature and osmotic conditions—  
comparison of all known *Bannoa* species.

\*, denotes assimilation data for *B. hahajimensis*, *B. syzygii*, *B. bischofia* and *B. ogasawarensis* taken from Hamamoto et al. (2002).

### 2.4.3 Mating intercompatibility experiments

Mycelium and clamp connections were observed in three of the crosses between isolates of *B. tropicalis* (Table 2.3). Basidium-like structures were observed after 42 days of incubation at room T in complete darkness on CMA (Figure 2.3). These structures resemble those described by Hamamoto et al. (2002) as basidia clamped at the base emerging laterally from the hyphae in *B. hahajimensis*. Basidia-like cells were obovoid to obpyriform ( $6 \times 3.5 \mu\text{m}$ ), sometimes with a slender apex. Single cultures of each strain, similarly incubated, did not develop similar structures. In experiments of intercompatibility incubated at 25 C under 12:12h light:darkness and incubated at 30 C under 12:12h light:darkness conditions, development of mycelium and clamp connections was not observed. Mycelium with clamp connections or basidia were not observed when isolates of *B. guamensis* (MCA4612) and *B. rosea* (MCA4647) were crossed with any of the eight isolates of *B. tropicalis*.

Figure 2.2 Mating in *B. tropicalis*. **A.** Conjugation of cells and germination tube (arrows) in the cross between MCA4667 (holotype) and MCA4648. Bar= 20  $\mu\text{m}$  **B.** Hyphae with clamp connections (arrows) Bar= 2  $\mu\text{m}$ . **C.** Basidium clamped at the base (arrow) Bar= 2  $\mu\text{m}$ , cross between MCA4644 and MCA4667 **D.** Basidium and hyphae with clamp connections (arrows) in cross between MCA4644 and MCA4667 Bar= 5  $\mu\text{m}$ .

Table 2.3 Intercompatibility cross results for ten strains of *Bannoa*

(-): Indicates no compatibility

(+): Indicates the development of hyphae and basidium-like structures.

## 2.5 Taxonomy

***Bannoa guamensis*** P.P. Parra & Aime, sp. nov.

FIGS. 2.4A, 2.4D

MycoBank: MB 823250

*Typification:* GUAM. MANGILAO: University of Guam campus, from a diseased leaf of *Bidens* sp. (Asteraceae), 31 Jan 2012, *M.C. Aime MCA4612* (**holotype** PUL F21058). Ex-type cultures NRRL Y-63976. GenBank: ITS = MK287350; 28S = MK255006; 18S = MK254996; *tef1* = MK491345.

*Etymology:* *guamensis* (Latin), referring to the geographical origin of the species.

*Description:* Asexual stage consisting of uninucleate cells that reproduce by monopolar or bipolar budding. After 7 days of culture in YM broth, cells ellipsoidal 4.5–6.5 × 2.5–4 µm, occurring singly or in parent-bud pairs. Ballistoconidia formed; neither true nor pseudo-hyphae on CMA formed. After 7 days at 25 C on YM agar, colonies orange in color (0ac631), smooth and glistening, butyrous (buttery) in texture. Colony form circular with entire margin and convex elevation. Sexual state unknown.

Fermentation ability negative. Growth was observed at 25 C and 30 C but not at 35 C. When cultured on media containing agar (2%), yeast extract (1%) and supplemented either with 50% glucose, 10% or 16% NaCl, growth was not observed. Assimilation positive for glucose, soluble starch, inulin, D-gluconate, myo-inositol, trehalose, turanose. Weakly assimilated compounds include 2-Keto-D-gluconate, arbutin, cellobiose, D-arabinose, D-mannitol, D-xylose, galactose, glycerol, L-arabinose, L-glutamic acid, L-rhamnose, maltose, melezitose, melibiose, raffinose, salicin and xylitol. Assimilation delayed positive or latent for lactose, methanol, ethanol, DL-Lactate, D-glucuronic acid, propane 1,2 diol. Assimilation of carbon compounds negative for: adonitol, aspartic acid, citrate, d-galacturonic acid, galactitol and succinate. Growth on L-lysine-HCl positive but weak when creatine and D-tryptophan was used as nitrogen sources. Growth negative on cadaverine, creatinine, D-glucosamine, and nitrite. Growth observed on vitamin free media.

*Notes:* *Bannoa guamensis* is morphologically indistinguishable from *B. hahajimensis* and *B. tropicalis*, which are the most closely related described species. However, several physiological differences were observed between these three species. Growth of *B. guamensis* in lactose, methanol and myo-inositol is positive unlike for *B. hahajimensis* and *B. tropicalis*. Assimilation of galactitol and L-sorbose is negative in *B. guamensis* but positive for both *B. hahajimensis* and

*B. tropicalis*. In addition, *B. guamensis* forms a unique phylogenetic position with respect to *B. hahajimensis* and *B. tropicalis*. Considering the most two variable loci, *B. guamensis* differs from *B. hahajimensis* by 2.3% (11/504 bp; ITS) and 2.6% (22/1015 bp; *tef1*). Sequence divergence between *B. guamensis* and *B. tropicalis* is 1.4% (7/504 bp; ITS) and 2.8% (23/1015 bp; *tef1*).

*Bannoa guamensis* is the first formally described species to be isolated from rust-diseased leaves and appears as a sister species to the ‘Uncultured fungus isolate OTU 118’ that was originally reported as *B. hahajimensis* by James et al. (2016) (Figure 1 and Figure 2). It is possible that rust sori may provide a microniche for this lineage, but at this time *B. guamensis* is known only from a single isolate.

***Bannoa rosea*** P.P. Parra & Aime, sp. nov.

FIGS. 2.4B, 2.4E

MycoBank: MB 823251

*Typification*: GUAM. HAGÅTÑA: Paseo Park, from asymptomatic undetermined leaf, Feb 2012, *M.C Aime MCA4647* (**holotype** PUL F21059). Ex-type cultures NRRL Y-63977. GenBank: ITS = MK287351, 28S = MK255007, *tef1* = MK491346.

*Etymology*: *rosea* (Latin), referring to the dark pink color of the colony.

*Description*: Asexual stage producing colonies dark pink in color (0ac619), corrugated, and butyrous in texture after 7 days at 25 C on YM agar. Colony form irregular with undulate margin and flat elevation. Uninucleate cells occurring singly or in parent-bud pairs, reproducing by polar budding. In YM broth single cells ellipsoidal, 9–10.5 × 4.5–6 µm after 7 days of incubation. Ballistoconidia formed. On CMA cultures neither pseudo nor true hyphae observed. Sexual stage unknown.

Fermentation of sugars is absent. Growth was observed at 25 C and 30 C but not at 35 C. When cultured on media containing agar (2%), yeast extract (1%) and supplemented either with 50% glucose, 10% or 16% NaCl, growth was not observed. Assimilation positive for glucose, D-glucuronate, myo-inositol, DL-lactate, 1,2-propanediol; slow growth on lactose. Weakly assimilated compounds include 2-keto D-gluconate, adonitol, cellobiose, D-gluconate, D-mannitol, D-melezitose, D-melibiose, D-sorbitol, D-xylose, L-arabinose, L-rhamnose, L-sorbose, maltose, melezitose, melibiose, raffinose, sucrose, trehalose, turanose and xylitol. Assimilation of carbon compounds negative for: citrate, D-arabinose, ethanol, methanol, salicin and succinate. Growth positive when L-lysine-HCl, D-glucosamine and D-tryptophan were used as nitrogen sources.

Growth negative on cadaverine, creatinine, D-glucosamine, and nitrite. Growth observed on vitamin free media.

*Notes:* *Bannoa rosea* does not assimilate D-glucosamine, citrate, salicin, glycerol, N-acetyl-D-and glucosamine, while assimilation is positive for *B. ogasawarensis*. *B. rosea* growth in vitamin free media is positive, while *B. ogasawarensis* does not. Sequences of the type strain MCA4647 of *B. rosea* diverge from the type strain JCM10326 of *B. ogasawarensis* by 2.5% (12/504 bp), 0.4% (2/557 bp) and 5.1% (44/1015) for the ITS, nuc 28S and the *tef1* region respectively. *Bannoa rosea* is similar in morphology to *B. ogasawarensis*, but is easily distinguished by its unique assimilation of carbon compounds (Hamamoto et al. 2002, Hamamoto 2011).

***Bannoa tropicalis*** P.P. Parra & Aime, sp. nov.

FIGS. 2.4C, 2.4F

MycoBank: MB 823249

*Typification:* GUAM. YIGO: Andersen Air Force Base, on rust infected leaf of *Bidens* sp. (Asteraceae), 01 Feb 2012, *M.C. Aime* MCA4667 (**holotype** PUL F21060). Ex-type cultures: CBS 16087 = NRRL Y-63978. GenBank accession: ITS: MK287360, D1–D2 domains of nuc 28S rDNA: MK255016, nuc 18S rDNA: MK255003, and *tef1*: = MK491353.

*Etymology:* *tropicalis* (Latin), referring to the pantropical distribution.

*Description:* Colonies of asexual stage orange (oac631) after 7 days at 25 C on YM agar and CMA; smooth, glistening, and butyrous in texture. Colonies circular with entire margin and convex elevation. In YM broth uninucleate single cells ellipsoidal to narrowly ellipsoidal,  $5.5\text{--}7 \times 2.5\text{--}4 \mu\text{m}$  after 7 days of culture. Ballistoconidia formed; both polar and bipolar budding present. Sexual stage mycelial, hyphae  $1.3$  to  $1.5 \mu\text{m}$  diam, clamp connections present; basidia  $6 \times 3.5 \mu\text{m}$ , obovoid to obpyriform, clamped at the base and sometimes with slender apex, produced after 42 days of incubation on CMA at room T in complete darkness.

Fermentation absent. Growth was positive at 25 C and 30 C and absent at 35 C. When cultured on media containing agar (2%), yeast extract (1%) and supplemented either with 50% glucose, 10% or 16% NaCl, growth was not observed. Assimilation positive for cellobiose, glucose. Assimilation delayed positive or latent for ethanol, galactitol, DL-lactate and D-glucuronic acid. Weakly assimilated compounds include 2-keto D-gluconate, adonitol, D-arabinose, D-gluconate, D-glucosamine, D- mannitol, D-xylose, galactose, glycerol, L-arabinose, L-glutamic acid, L-rhamnose, L-sorbose, maltose, melezitose, melibiose, N-acetyl-D glucosamine, raffinose, salicin,

sucrose, trehalose, turanose and xylitol. Assimilation of carbon compounds negative for 1,2 propane diol, arbutin, aspartic acid, citrate, D- galacturonic acid, lactose, methanol, succinate. Growth on L-lysine-HCl positive, but latent or delayed when D-tryptophan was used as a nitrogen source. Weakly growth on cadaverine, creatine, creatinine and nitrite (NaNO<sub>2</sub>). Growth is observed on vitamin free media.

*Other specimens examined:* GUAM. HAGÅTÑA: Paseo Park, asymptomatic undetermined leaf, 01 Feb 2012, *M.C. Aime MCA4620* (PUL F24076); Paseo Park, from Palm trash swap, 01 Feb 2012, *M.C. Aime MCA4643* (PUL F24077); Paseo Park, from *Puccunia lepturi* diseased leaf of *Lepturus repens* (Poaceae), 01 Feb 2012, *M.C. Aime MCA4644* (PUL F24078); Paseo Park, from asymptomatic undetermined leaf, 01 Feb 2012 *M.C. Aime MCA4646* (PUL F24080); Paseo Park, from asymptomatic undetermined leaf, 01 Feb 2012, *M.C. Aime MCA4648* (PUL F24081). YIGO: Bernhard's Farm, *Kweilingia* sp. symptomatic leaf of a plant in Poaceae, 01 Feb 2012, *M.C. Aime MCA4645* (PUL F24079). GUYANA. REGION 9 UPPER TAKUTU-UPPER ESSEQUIBO/ANNAI: Rock View Lodge, from asymptomatic undetermined leaf, 28 Dec 2013, *M.C. Aime MCA5562* (PUL F24082).

*Notes:* *Bannoa tropicalis* has been isolated from rust-infected leaves in the Western Pacific and neotropical regions. *Bannoa tropicalis* assimilates inulin and grows on media containing nitrite and cadaverine is positive (weak) as nitrogen source, while growth is negative on *B. hahajimensis* and *B. guamensis*. Growth in vitamin free media is positive; and assimilation is negative for citrate, succinate if compared only to *B. hahajimensis*. Percentages of divergence between *B. tropicalis* and *B. hahajimensis* are 0.15% (2/1387 bp), 1.7% (9/504 bp), 0.6% (3/557 bp) and 3.2% (27/1015 bp) for the 18S, ITS, nuc 28S and the *tef1* respectively.

Figure 2.3 Colony and cell morphology of new species of *Bannoa*. **A, D.** *B. guamensis* MCA4612<sup>T</sup>. **B, E.** *B. rosea* MCA4647<sup>T</sup>. **C, F.** *B. tropicalis* MCA4667<sup>T</sup>. Bars: 10 µm. A, B, C and D, E, F were grown on YMA and YMB, respectively, for seven days at room temperature.

## 2.6 Discussion

In this study, the analysis of three- and four-locus phylogenies allowed to delineate at least nine species-level lineages, three of which we describe as new: *B. guamensis*, *B. rosea* and *B. tropicalis*. Other two species-level lineages from environmental sampling may represent new species; the first lineage appears as closely related to *B. syzygii* and comprises accessions AJ222810.1 and AJ289868.1 isolated from *Miscanthus* sp. and *Miscanthus sinensis*, respectively. The second lineage, comprises the sequence KT328804.1 that was obtained from sori of the coffee rust *Hemileia vastatrix* (James et al. 2016) and appears as sister species to *B. guamensis* that was isolated from a diseased leaf of *Bidens* sp. Furthermore, our data indicate that *B. tropicalis*, *B. guamensis*, and environmental isolates can be isolated from rust sori and may be co-inhabitants of this microniche during the yeast stage. Of the 12 strains collected in Guam in 2012 and the one collected in Guyana during 2013, seven (or 58%) were associated with diseased leaves (Table 2.1); however, in other studies strains of species in *Bannoa* have been reported from asymptomatic and

dead leaves (Nakase et al. 2001, Hamamoto et al. 2002). Other species such as *Symmetrospora oryzicola* and *Symmetrospora coprosmae*, *Erythrobasidium hasegawianum* and *Hasegawazyma lactosa* are also found in association with other fungi (Hamamoto et al. 2002, Sampaio 2011, James et al. 2016) but the nature of this interaction is unknown. Other species in the Cystobasidiomycetes such as *Naohidea sebacea*, *Cystobasidium fimetarium* and *Occultifur internus* have been found parasitizing other fungi during their sexual hyphal stage (Roberts 1999, Piatek 2002, Bauer et al. 2006). The results obtained from our intercompatibility studies support the reproductive isolation of the three newly described species *B. tropicalis*, *B. rosea* and *B. guamensis*. Among *B. tropicalis*, the intercompatible crosses indicate that a bifactorial mating system is the most likely system that governs cell identity in this species. We detected at least three mating types; the first mating type comprises strain MCA4667 (A1B1), the second strains MCA4644, MCA4646 and MCA4648 (A2B2) and a third mating type formed by strains MCA4620, MCA4643, MCA4645 and MCA5562 (A1B2/A2B1). According to Coelho et al (2017), in a bifactorial mating system the chances of haploid cells from the same diploid parent are compatible is at most 25%, compared to 50% in an unifactorial mating system. If it were the case of *B. tropicalis*, we could have expected a higher proportion of crosses in which hyphae, clamp connections and basidium were observed. As strain MCA4667 was compatible with other three strains. Similar results were reported by Hamamoto et al (2002), when four strains of *B. hahajimensis* were crossed. A multiallelic bifactorial mating system was suggested to govern sexual identity. Although we only observed a hyphal stage in strains of *B. tropicalis* under laboratory conditions (Figure 2.3), it is uncertain whether the hyphal stage commonly occurs in natural conditions and if this is a mechanism either to reach resources or to interact with other fungi affecting the host plant. As several species in the Cystobasidiomycetes have been shown to be mycoparasites, the association of *Bannoa* with other rust fungi may provide another piece of evidence to hypothesize that dimorphic species in the genus could become parasitic during their dikaryotic hyphal stage.

It has been demonstrated that the description of new species from single strains often leads to a cascade of reported isolations from other locations and substrates (Schelenz et al. 2016, Smith et al 2017, Kijpornyongpan et al. 2018). Here, the description of these three species of *Bannoa* allowed to expand the known range of *Bannoa* westward to South America and southward to Guam. We report new associations and microhabitats of the genus besides *Hemileia vastatrix*-infected leaves of coffee (James et al. 2016), for example *B. tropicalis* can also be found in *Kweilingia* sp.-

infected leaves of an unidentified plant, *Uromyces* sp.-infected leaves of *Bidens* sp. and finally *Puccinia lepturi*-infected leaves of *Lepturus* sp. The description of new species from under sampled geographic regions and microhabitats, is essential to enlarging our knowledge of the scope and distribution of fungal diversity (Graff 1917, Case et al. 2012, Kijpornyongpan and Aime 2016) as is the case for the genus *Bannoa*.

## CHAPTER 3. NEW SPECIES IN THE CYSTOBASIDIOMYCETES

### 3.1 *Buckleyzyma butyroza* and *Sakaguchia warrensis*: new species in the Buckleyzymaales and Sakaguchiales

#### 3.1.1 Abstract

*Buckleyzyma* and *Sakaguchia* are two small genera in the Cystobasidiomycetes with five species each. Both genera contain pink or red pigmented yeast species with different host associations ranging from the gut of beetles and salmonids to marine habitats. New species have not been described in the last 31 and eight years in *Buckleyzyma* and *Sakaguchia*, respectively. In the present study we describe *Buckleyzyma butyroza* and *Sakaguchia warrensis* isolated from non-volumetric air sampling in Maryland and Indiana, USA. We include morphological, physiological and sequences of the nuclear rDNA ITS1-5.8S-ITS2 (ITS), D1–D2 domains of nuclear 28S rDNA (28S), nuclear 18S rDNA (18S) and the RNA polymerase II subunit *rpb2*. Previous phylogenetic studies focused on generating and including molecular data of several loci for the type strains of extant species, but little has been done to correctly classify and increase the knowledge we have about the biology, distribution and host associations of species in both genera. For that reason we, we compiled available information including sequences from cultures, environmental samplings, geographic distribution and substrate that are available in the NCBI and literature to expand our knowledge of these two understudied genera.

#### 3.1.2 Introduction

*Rhodotorula* and *Sporobolomyces* are artificial genera of mostly pink or red pigmented yeasts, many of which belong in Cystobasidiomycetes (Aime et al. 2014). Within Cystobasidiomycetes these have been placed within several informally named clades: Aurantiaca, Magnisporus, Marina, and Sakaguchia (Aime et al. 2006, Bauer et al. 2006, Wang et al. 2015a). Several studies have focused on the reevaluation of red yeast species, stimulated by the one name one fungus nomenclature in accordance with the International Code of Nomenclature for algae, fungi, and plants (McNeill et al. 2012). It has been shown that *Sporobolomyces* and *Rhodotorula sensu stricto* are allied within Sporidiobolales (Mycobotriomycetes) (Fell et al. 2000, Scorzetti et al. 2002, Boekhout et al. 2011, Sampaio 2011, Wang et al. 2015b), thus, those species of *Sporobolomyces* in the Marina, Magnisporus and Aurantiaca groups have been placed in the new genera

*Symmetrospora*, *Microsporomyces* and *Buckleyzyma*, respectively, while species of *Rhodotorula* in the *Sakaguchia* group were recombined into *Sakaguchia* (Wang et al. 2015b). While these generic-level relationships have been resolved, the positions of these genera within Cystobasidiomycetes have not been determined (Wang et al. 2015b). The first species to be described in what is now the genus *Buckleyzyma* was originally described in 1922 as *Torula aurantiaca*, isolated from air sampling in Japan. Other strains that appear conspecific with *B. aurantiaca* have been isolated from *Elaeagnus multiflora* and *Pyrus serotina* var. *culta* in South Korea, from lake water in China and from unidentified plants in China, Portugal and Australia (Wuczkowski and Prillinger 2004). Another species, *Buckleyzyma armeniaca*, was isolated from *Banksia colina* in Australia (Shivas and Rodrigues de Miranda 1983) and is the only reported strain for the species. The following year, in 1984, *B. salicina* was described from *Salix* sp. in Canada by Johri and Bandoni, also other strains have been isolated from the phylloplane of *Cotoneaster* sp. in China, from *Vitis vinifera* leaves in USA, from mangrove sediments in India, from forest litter in Austria and from an unidentified plant in Portugal (Wuczkowski and Prillinger 2004, Bourret et al. 2013, Velmurugan et al. 2013). In 1986, *B. kluyveri-nielii* was originally isolated from *Dombeya rotundifolia* in South Africa (Van Der Walt et al 1986), but later, several strains were isolated from mangrove sediments in India (Velmurugan et al. 2013). The last species in the genus to be described is *B. phyllomatis*. This species was originally described as *Sporobolomyces phyllomatis* and isolated from *Dombeya rotundifolia*. *Buckleyzyma* species produce pink-salmon to orange colonies with ellipsoidal to cylindrical cells that in general appear singly or in parent-bud pairs. However, in *B. phyllomatis*, cells sometimes appear organized in small clusters. Production of ballistoconidia and pseudohyphae have been reported in *B. kluyveri-nielii*, *B. phyllomatis* and *B. salicina* but are absent in *B. armeniaca* and *B. aurantiaca*. Rudimentary septate hyphae are observed in *B. kluyveri-nielii* while in *B. phyllomatis* the hyphae were described as adventitiously septate delimited by terminal lipid-rich cells (Van Der Walt et al 1986, 1988). In both cases, hyphae were produced in single-cell cultures on corn meal agar (CMA, Difco) (Van Der Walt et al. 1986, 1988). Clamp connections have not been observed in any of the described species in *Buckleyzyma*.

Like *Buckleyzyma*, *Sakaguchia* is a small genus with only five species. In 1973, *S. dacryoidea* was described as *Rhodosporidium dacryoidum* and was first isolated from sea water in the Antarctic Peninsula (Fell et al. 1973). Subsequently, other strains of *S. dacryoidea* have been

isolated from mangrove sediments, seawater and fresh water in Antarctica, India, New Zealand and Portugal (Almeida and Sampaio 2003, Velmurugan et al. 2013, Francis et al. 2016) and from seawater and the gut of fish from environmental sequencing studies in China and Chile (Raggi et al. 2014, Yu et al. 2017). Several years later in 2001, *S. lameliibrachiae*, first described as *R. lamellibrachii*, was isolated from a tube worm (*Lamellibrachia* sp.) at a depth of 1156 m in Sagami bay, Japan (Nagahama et al. 2001). Other reports of *S. lameliibrachiae* are from environmental sampling from sea water in China (Yu et al. 2017). *Sakaguchia orzyae* was first isolated in Japan from paddy rice and was originally described as *R. oryzae* in 2003. In more recent years, *S. meli* was described from the Argentinean Patagonia (Libkind et al. 2010), while other strains have been isolated from fresh water, from soil in USA and from a glacial lagoon in Argentina. This latest strain has been classified as *Rhodotorula* sp. (Libkind et al. 2003). Lastly, *S. cladiensis* was isolated from fresh water and mangrove habitat in Florida bay (Fell et al. 2011). This species is only known from this location.

Species in *Sakaguchia* share several macro- and micromorphological characteristics with species in *Buckleyzyma* and other genera in the Cystobasidiomycetes such as colored colonies that range from pink, orange to red and in some species single cells are arranged in parent-bud pairs. Cell shape can be ovoidal, ellipsoidal or cylindrical. Hyphae or pseudohyphae are not formed, however cells of *S. cladiensis* and *S. dacryoidea* can be found in short chains (Fell et al. 1973, 2011). Development of sexual structures and hyphae with clamp connections has only been observed in *S. dacryoidea* (Fell et al. 1973). New species have not been described during the last 31 and eight years in *Buckleyzyma* and *Sakaguchia*, respectively, nonetheless, there are several sequences from next-generation sequencing studies and strains isolated from fungal community studies that show new host associations with insects like *Diabrotica virgidera* and *Atta texana* (Molnár et al. 2008, Rodrigues et al. 2009, Poli et al. 2018) in species of *Buckleyzyma*. Additionally next-generation sequencing studies also show several sequences in species of *Sakaguchia* associated with fish like *Cillius gilberti* (Raggi et al. 2014).

*Buckleyzyma* and *Sakaguchia* remain understudied, as is true for other genera in the Cystobasidiomycetes, and their role in nature remains unknown. Phylogenetic studies have focused on generating and including molecular data of several loci for the type strains of extant species, but little has been done to increase the knowledge we have about their biology, host associations and habitat preference. We compiled the available information that has been generated

in recent years from different studies, including several unclassified accessions in the NCBI database that are key to understanding geographical distribution and new host associations of species in these two genera. Lastly, during field collections performed in Maryland and Indiana, United States, several strains of pink and orange pigmented yeast were isolated by using the non-volumetric air sampling methodology. In this paper, we present morphological, physiological and phylogenetic analysis based on four loci of the known species and describe two new species, *B. butyrosa* and *S. warrensis*. Also, we report the occurrence of *B. salicina* in the United States, that has only been reported before from *Vitis vinifera* inflorescences in Washington state (Bourret et al. 2013). these findings do not only indicate a wider distribution but also new host associations of this species.

### 3.1.3 *Material and Methods*

#### 3.1.3.1 *Sample collection and storage*

Three strains were obtained by using the non-volumetric sampling method (that consists in leaving a petri plate with culture media and without a lid for a determined period of time) in Maryland in 2003 and Indiana in 2013 and 2015. For JDSF10, we used 50% glucose medium. Cultures were maintained on potato dextrose agar (PDA; 39g/L, Livonia, Michigan) slants at 4 C for short-term storage and in 40% glycerol vials at -80 C for long-term storage. Cultures of the isolates MCA2993, P117 and JDSF10 were dried and deposited as holotypes in the Kriebel Herbarium (PUL). Living cultures also were deposited in the Westerdijk Fungal Biodiversity Institute (CBS) and the Fungal Biodiversity Center and Agricultural Research Service (NRRL).

#### 3.1.3.2 *Morphological and physiological studies*

To study macro- and micromorphological features of the collected strains, they were cultured on yeast malt agar (YMA, Difco, Franklin Lakes, New Jersey), yeast malt broth (YM broth, Difco) and corn meal agar (CMA, Difco) at 25 C for seven days. Features such as color of the colonies, cell shape and cell measurement, was performed as in section 2.3.2. Equipment used for cell morphology studies consisted of a compound microscope, OLYMPUS BH-2 (Olympus, Japan) under phase-contrast microscopy. Assimilation of carbon and nitrogen compounds as well as fermentation tests were performed in liquid media, while growth of strains on high osmotic media and growth on vitamin-free media were performed in solid media according to Kurtzman et al.

(2011). Likewise, the ability of strains to grow on other carbon sources was assessed by using a Yeast Identification Test Panel (Biolog Inc., Hayward, California) as performed in Kijpornyongpan and Aime (2017).

### **3.1.3.3 DNA extraction and phylogenetic studies**

DNA extraction was performed from pure cultures grown on YMA using the Promega Wizard genomic DNA purification kit (Promega, Madison, WI). Phylogenetic placement of newly collected strains was inferred from sequences of the internal transcribed spacer (ITS) bar code region (nuc rDNA ITS1-5.8S-ITS2), D1–D2 domains of the nuc 28S rDNA (28S), the nuc 18S rDNA (18S) and the RNA polymerase II subunit *rpb2*, with primers ITS1F (Gardes and Bruns 1993) and ITS4 (White et al. 1990b), LR0R/LR5 (Vilgalys and Hester 1990), NS1/NS4 and NS3/NS8 (White et al. 1990b) and 5F/6R1 and 6F/7CR (Liu et al. 1999), respectively. PCR programs for amplification were followed according to section 2.3.4. PCR products were separated in a 1% agarose gel and sent to GENEWIZ (South Plainfield, New Jersey) for sequencing. Sequences were edited using GENEIOUS 9.1.2 (Biomatters, Auckland, New Zealand). All available sequences of the 18S, ITS and 28S from environmental sequencing and collections from previous studies for species in *Buckleyzyma* and *Sakaguchia* were aligned in two different datasets. Ambiguously aligned regions for each locus were removed with Gblocks using the less stringent selection option (Talavera and Castresana 2007). Two datasets consisting of four loci were generated: The first dataset was generated for the phylogenetic analysis of species in *Buckleyzyma*, while another dataset was used for the phylogenetic reconstruction of *Sakaguchia*. Taxon sampling consisted of sequences of the ITS, 28S and 18S of type strains of extant species in *Buckleyzyma* and *Sakaguchia*; were used to run a BLASTN search against the NCBI GenBank database, sequences from culture collections and environmental samplings were included in the analysis. *Naohidea sebacea* was used as outgroup (Aime et al. 2006) in both analyses. Sequences for each locus were first aligned with MAFFT 7.222 (Katoh et al. 2002) using the L-INS-I algorithm. Subsequently, alignments of the four loci used were concatenated using GENEIOUS 9.1.2 (Biomatters, New Zealand) to perform the multi-locus phylogenetic reconstruction.

The General time reversible model with substitution-rate among sites of gamma distribution (GTR+G) was selected as the substitution model of evolution for both datasets according to

PARTITIONFINDER2 based on the Akaike Information Criterion (AIC) (Stamatakis 2014, Lanfear et al. 2012, 2016). Phylogenetic reconstruction was performed using Maximum Likelihood (ML) followed by 1000 bootstrap replicates using GENEIOUS 9.1.2. Bootstrap proportions (BP) are reported below. Bayesian inference (BI) was performed using MRBAYES 3.2.6 (Huelsenbeck and Ronquist 2012) with a GTR model, nts:6, rates=invgamma according and five million generations. The first 25% of trees were discarded as Burn-in.

### 3.1.4 Results

#### 3.1.4.1 Phylogenetic placement of collected strains

The first dataset for *Buckleyzyma* was composed of 1668, 580, 596 and 658 bp while the second dataset for *Sakaguchia* was composed of 1024, 540, 486 and 674 bp for the nuc 18S, ITS, nuc LSU and the *rpb2* sequences, respectively. The four concatenated loci consisted of 3502 bp for *Buckleyzyma* and 2724 bp for *Sakaguchia* phylogenetic reconstruction. The multi-locus phylogenetic reconstruction along with morphological and physiological data support two new species: *Buckleyzyma butyrosa* and *Sakaguchia warrensis*.

*Buckleyzyma butyrosa* appears as phylogenetically related to *B. armeniaca* and *B. phyllomatis* (Figure 3.1). Neither molecular data from culture collections nor environmental sequences appear clustered together with *B. butyrosa*. Our phylogenetic analysis shows several unclassified sequences that belong to already described species in the genus such as *B. aurantiaca*, *B. salicina* and *B. kluyveri-nielli*. Likewise, a cluster of sequences that appear as sister species of *B. aurantiaca* may represent a new species. Strain P117 isolated from air sampling belongs to *B. salicina* and appears as the second known report of this species in the USA.

For *S. warrensis*, only one sequence from environmental sampling (Uncultured fungus clone CMH332) in the United States from indoor environments appears conspecific (Figure 3.2). In our phylogenetic analysis, several independent evolutionary lineages that may represent new species are identified. Additionally, several accessions retrieved from the NCBI had incorrect names.

Figure 3.1 Phylogenetic reconstruction of *Buckleyzyma* inferred from concatenated sequences of ITS, D1–D2 domains of nuclear 28S, nuclear 18S rDNA, and *rpb2* using maximum likelihood.

New species indicated in bold. Posterior probability (PP > 0.7) and bootstrap support (BP > 50%) values are shown above nodes. ns: not supported. Tree is midpoint rooted. Scale bar equals expected number of substitutions per site. Strain number is listed in front of the taxon name. <sup>T</sup> denotes type species strain.

Figure 3.2 Phylogenetic reconstruction of *Sakaguchia* inferred from concatenated sequences of ITS, D1–D2 domains of nuclear 28S, nuclear 18S rDNA, and *rpb2* using maximum likelihood.

New species indicated in bold. Posterior probability (PP > 0.7) and bootstrap support (BP > 50%) values are shown above nodes. ns: not supported. Tree is midpoint rooted. Scale bar equals expected number of substitutions per site. Strain number is listed in front of the taxon name. <sup>T</sup> denotes type species strain.

### 3.1.5 Taxonomy

***Buckleyzyma butyrosa*** P.P. Parra & Aime, sp. nov.

FIGS. 3.3A, 3.3C

MycoBank: MB 831219

*Typification:* UNITED STATES. MARYLAND: Prince George County, aerial sampling, 16 September, 2005. *M.C. Aime MCA2993*. (**holotype** PUL: F24083). Ex-type cultures CBS 16088 (NRRL Y-63999). GenBank: ITS = MK990657, D1–D2 domains of nuc 28S rDNA = MK990684, nuc 18S rDNA = MK990638.

*Etymology:* Referring to the buttery texture of the colony.

*Description:* After 7 days at 25 C on YM agar colonies orange colored (0ac651), dull surface and butyrous in texture. Colony form is irregular with entire margin and crateriform elevation. Cells occur singly or in parent-bud pairs and reproduce asexually by multilateral budding. In YM broth (YM broth, Difco) after 7 days, cells are ellipsoidal to narrowly ellipsoidal  $3\text{--}4.7 \times 6.8\text{--}9.5\ \mu\text{m}$  with some pyriform cells. On CMA agar, colonies are orange in color (0ac652), neither true nor pseudohyphae are formed. Ballistoconidia were not observed.

Fermentation is absent. Growth is observed at 25 C and absent at 30 C and 35 C. When cultured on media containing agar (2%), yeast extract (1%) and supplemented either with 50% glucose, 10% or 16% NaCl colonies were not formed. Growth is observed on vitamin free media. The following carbon compound are assimilated: 1,2-propanediol, dextrin, dextrin + xylose, glucose, D-glucuronate, DL-lactate (slow), lactose (slow) and methanol. Weakly assimilated compounds are: 1,2-propanediol + xylose,  $\alpha$ -D-glucose,  $\alpha$ -D-lactose + xylose, arbutin,  $\beta$ -Me-D-glucoside, cellobiose, D-gluconic acid, inulin, D-galactose, D-melezitose, D-psicose, D-mannitol, D-sorbitol, D-arabitol, L-aspartic acid, D-arabitol, D-galactose, D-galactose + xylose, D-gluconic acid, D-glucuronic acid + xylose, D-mannitol, D-melibiose + xylose, D-sorbitol, D-xylose, gentiobiose, inulin, L-sorbose, m-inositol + xylose, glycerol, maltotriose, L-arabinose, L-glutamic acid, L-sorbose, NAc-L-glutamic acid, L-proline, maltose, Me-succinate + xylose, mentiobiose, salicin, succinic acid, sucrose, palatinose, propionic acid and xylitol. Nitrogen assimilation on D-Glucosamine, D-Tryptophan and L-lysine-HCl (slow) are positive (Table 3.1).

*Notes:* Assimilation of carbon compounds of *Buckleyzyma butyrosa* is positive in methanol, weak for cellobiose, D-gluconic acid, inulin, salicin and sucrose and slow for lactose if compared with its sister species *Buckleyzyma armeniaca* for which growth is negative. When sequences of *B. butyrosa* are compared to *B. armeniaca*, sequences divergence is 0.24% (4/1668 bp, no gaps), 2.7%

(16/580 bp, two gaps), 0.2 % (1/596bp, no gaps) and 11% (73/658 bp, two gaps) for the nuc 18S, ITS, nuc 28S and the *rpb2* respectively.

*Sakaguchia warrensis* P.P. Parra & Aime, sp. nov.

FIGS. 3.3B, 3.3D

MycoBank: MB 831220

*Typification*: UNITED STATES. INDIANA: Warren county, isolated from non-volumetric sampling in media containing 50% glucose in the Weiler-Leopold Nature reserve. Collected during the A. H. Smith Great Lakes States Foray. September 27, 2015. *Jorge Diaz-Valderrama, JDSF10*. (**holotype** PUL: F24088). Ex-type cultures CBS 16089 = NRRL Y-64000. GenBank: ITS = MK990682, D1–D2 domains of nuc 28S rDNA = MK990698, nuc 18S rDNA = MK990648.

*Etymology*: Referring to the Warren County located in western Indiana, United States between the Illinois State line and the Wabash River where the strain was collected.

*Description*: After 7 days at 25 C on YM agar colonies salmon colored (0ac617), glistening surface and butyrous in texture. Colony form circular with curled margin and umbonate elevation. Cells occur singly or in clusters and reproduce asexually by multilateral budding. In YM broth (YM broth, Difco) after 7 days, cells are oblong,  $2.3\text{--}3.4 \times 4.2\text{--}8.6 \mu\text{m}$ . On CMA agar, colonies are orange in color (0ac618).

Growth was observed at 25 C and 30 C but not at 35 C. When cultured on media containing agar (2%), yeast extract (1%) and supplemented either with 50% glucose, 10% or 16% NaCl growth was not observed. Growth on vitamin free media is positive. Assimilates 1,2-propanediol, dextrin, D-glucuronate, DL-lactate, glucose, and soluble starch. Assimilation of carbon is weak for the following compounds: 2-keto D-gluconate,  $\alpha$ -D-glucose,  $\alpha$ -Me-D-glucoside, adonitol, amygdalin,  $\beta$ -Me-D-glucoside, bromosuccinic acid, cellobiose, D-psicose, D-arabinose, dextrin + xylose, gamma-aminobutyric acid, D-arabitol, D-galactose + xylose, D-gluconic acid, inulin, D-glucuronic acid + xylose, D-mannitol, D-melezitose, D-sorbitol, D-xylose, dextrin, fumaric acid, gentiobiose, glycerol, guinic acid + xylose, inulin, Me succinate, Me-succinate + xylose, L-glutamic acid, L-sorbose, maltitol, maltose, maltotriose, mentiobiose, palatinose, ribose, sucrose, trehalose, turanose, sucrose, tween 80, trehalose, xylitol. Assimilation of nitrogen on ethylamine-HCl, L-lysine-HCl, D-glucosamine and D-tryptophan is positive, weak growth in cadaverine-HCl and slow on D-galacturonate and methanol (Table 3.1).

*Notes: Sakaguchia warrensis* growth is positive in DL-lactate and soluble starch; weak in 2-keto D-gluconate, D-ribose, D-xylose, inulin, L-sorbose, slow in D-galacturonate and methanol while is negative for *Sakaguchia cladiensis* which is the sister species. Comparison of *S. warrensis* and *S. cladiensis* sequences show a divergence of 0% (0/1024 bp no gaps), 1.6% (9/540 bp, no gaps), 2.9% (14/486 bp, 5 gaps) and 9.19% (62/674 bp, no gaps) for the 18S, ITS, nuc 28S and the *rpb2* respectively.

Figure 3.3 Colony and cell morphology. **A. C.** *Buckleyzyma butyrosa* MT254<sup>T</sup>. **B. D.** *Sakaguchia warrensis* SFJD10<sup>T</sup>. Bars: 20  $\mu$ m. A, B, and C, D, were grown on YMA and YMB, respectively, for seven days at room temperature.

Table 3.1 Assimilation of carbon and nitrogen compounds and growth under different temperature and osmotic conditions of new species of *Buckleyzyma* and *Sakaguchia* and sister species.

### 3.1.6 Discussion

The number of sequences available in the NCBI for genera like *Buckleyzyma* and *Sakaguchia* is significantly smaller if compared with those of *Cryptococcus* or *Bullera* that are commonly isolated from the phylloplane (Fonseca and Inácio 2006). However, several strains and sequences from environmental studies in *Buckleyzyma* and *Sakaguchia* have been reported in recent years that allow the inference of new habitats for species in both genera (Table 3.2, Table 3.3). *Buckleyzyma aurantiaca* was originally obtained from air sampling for which a substrate or host was not possible to establish at that time; in recent days several other strains and sequences of *B. aurantiaca* have been reported from roots of *Populus* sp. (Bourdel et al. 2016), the gut of insects and marine algae (Stefani et al. 2016). Species in *Buckleyzyma* have been traditionally found associated with the phylloplane of different families such as Elaeagnaceae, Malvaceae, Proteaceae, Salicaceae and Vitaceae, however, the host associations observed in the genus are not exclusive with plants but also have been isolated from mangroves or soils and other substrates.

Among the four loci, the 28S region presented the least divergence (0.2%) when *B. butyrosa* was compared with its sister species *B. armeniaca*, nonetheless there was a higher divergence for the ITS (2.7%) and the *rpb2* (11%) locus that provided more resolution in differentiating *B. butyrosa* from its closest relative. The use of *rpb2* in addition to the 18S, ITS and 28S region, was more useful in providing more phylogenetic resolution in the case of *Buckleyzyma*, when the 28S did not allow to separate *B. butyrosa* from *B. armeniaca*. Assimilation of nitrogen and carbon compounds of *B. butyrosa* shows several differences to *B. armeniaca*, its closest related species. Also, we provide additional physiological data by testing other compounds that were not assessed before in other species of the genus.

Our second described species is *S. warrensis* isolated from 50% glucose medium during non-volumetric air sampling. The fact that this strain was isolated from a high-osmotic pressure medium may indicate that this is a xerotolerant species, however, in subsequent attempts to culture the strain in media containing 10% NaCl and 50% glucose it failed to grow. The sequence divergence of the 28S region and the *rpb2* was 2.9% and 9.2% when *S. warrensis* was compared with *S. cladiensis*. The sequence divergence of 28S was higher (2.9%) in *S. warrensis* when compared with *S. cladiensis* than it was between *B. butyrosa* and *B. cladiensis* (0.2%), however, the divergence of the *rpb2* sequences in both cases was similar (11% and 9.2% in *Buckleyzyma* and *Sakaguchia* respectively). Both species, *B. butyrosa* and *S. warrensis*, were formally described

from single strain collections and since strains MCA2993 and JDSF10 of *B. butyrosa* and *S. warrensis* respectively, were obtained from non-volumetric air sampling a host is not recognized but this will serve as a reference for future strains or sequences that may be conspecific and help to better understand the host associations of these two species. Our analyses did not identify any other sequences that appear to be conspecific to *B. butyrosa*. However, there is one ITS sequence that was isolated from house dust in the United States that appears to represent *S. warrensis* (Accession: KF800423) (Rittenour et al. 2014). This study contributes not only with the description of new species in both genera, but also provides a more complete physiological profile and features that may have not been documented in species already described in both genera. Lastly, we document in this paper the second report of *B. salicina* (P117) from *Pinus nigra* in the United States enlarging the known geographic distribution of this species; the other reported strain in the country was isolated from *Vitis vinifera* inflorescences (Bourret et al 2013). *Bucklezyma salicina* also has been isolated from *Salix* sp. from Canada and from the phylloplane in China and Portugal (Inácio et al 2002). Apart from plants this species has been isolated from mangrove sediments in India (Velmurugan 2013). The description of new species from a single strain has been controversial, but several authors have provided arguments in favor to circumvent the major concerns of this practice (Graff 1917, Kurtzman and Robnett 1998, Kurtzman 2010, Case et al. 2012, Kijpornyongpan and Aime 2016). For example, the use of multigene comparison for the description *B. butyrosa* and *S. warrensis* has been a useful tool to get more phylogenetic resolution when single-gene phylogenies do not allow it.

### **3.2 *Halobasidium umbonatum* sp. nov. and the first report of *H. xiangyangense* in North America**

#### **3.2.1 Abstract**

The Cystobasidiales is one of the five orders in the Cystobasidiomycetes with a single family. This order includes *Cystobasidium*, *Occultifur* and the recently described *Halobasidium*. The genus *Halobasidium* with one species *H. xiangyangense*, was described from a traditional high-salt fermented food in China. In this study we used morphological, physiological and DNA sequences of the nuc rDNA ITS1-5.8S-ITS2 (ITS), D1–D2 domains of nuc 28S rDNA (28S), nuc 18S rDNA (18S) and the protein coding genes RNA polymerase II subunit *rpb2* and the cytochrome b *cytb* to propose *Halobasidium umbonatum*. A single strain MT254 of this species was isolated from

*Gymnosporangium* sp. infected leaves of *Crataegus* sp. Previous reports of sequences conspecific with *H. xiangyangense* are from China, Korea and Brazil, for which this is the first report in North America. Isolates RK86 and SA444 were obtained from *Dryopteris erythrosora* and watermelon skin.

### 3.2.2 Introduction

The Cystobasidiales includes anamorphic and dimorphic yeasts in a single family, the Cystobasidiaceae, comprises three genera: *Cystobasidium*, *Halobasidium* and *Occultifur* (Roberts 1997, Bauer et al. 2006, Guo 2019). The sexual stage of species of *Cystobasidium* and *Occultifur* are morphologically similar in terms of the formation of mycelium with clamp connections and their septal pore structure, which is occluded by a peculiar organelle called the cystosome (Weiss 2004, Sampaio et al. 1999). A sexual stage is not known in *Halobasidium*. Among the species in the Cystobasidiales in which a hyphal stage has been described are *C. fimetarium*, *C. sebaceum*, *C. proliferans*, *O. corticorum*, *O. externus*, *O. internus* and *O. kilbournensis* (Martin 1939, Olive 1952, Olive 1954, Roberts 1997, Roberts 1999, Sampaio et al 1999, Kurtzman and Robnett 2015). For the remaining species in *Cystobasidium*, *Halobasidium* and *Occultifur* only the asexual yeast stage has been reported, mostly exhibiting orange to pink colonies when cultured on artificial media.

Species in the Cystobasidiales have been isolated from habitats ranging from tropical regions to Antarctic environments, from marine to fresh water and terrestrial ecosystems, living presumably as saprobes on the surface of leaves, or as endophytes in the xylem of pine trees (Zhao et al. 2002). Also they have been isolated from plant litter, the rhizosphere or found associated with animals and parasitizing other fungi (Reiersøl 1954, Roberts 1999, Zhao et al. 2002, Nagahama et al. 2003, Satoh et al. 2013, Khunnamwong et al. 2015, 2017) or from fermented food as in *Halobasidium*, in which *H. xiangyangense* is considered a high-salt tolerant species. (Guo et al. 2019). During the last 10 years with the help of recent advances in molecular systematics it has been possible to phylogenetically place and describe species new in *Cystobasidium* and *Occultifur* and also to identify several sequences of isolates in independent evolutionary lineages within the Cystobasidiales. Most of these unclassified sequences correspond to the nuclear rDNA ITS1-5.8S-ITS2 (ITS barcode) and the D1–D2 domains of nuclear 28S rDNA (28S) and were generated from environmental samplings but many others correspond to isolates kept in private culture collections.

In the present study, based on morphological, physiological and molecular data we propose a new species namely, *Halobasidium umbonatum* sp. nov., isolated from *Gymnosporangium* sp. infected leaves of *Crataegus* sp. and also, we report for the first time in the western hemisphere *H. xiangyangense* isolated from *Dryopteris erythrosora* and watermelon skin.

### 3.2.3 *Materials and Methods*

#### 3.2.3.1 *Sample collection and storage*

The spore-drop method described in Toome et al. (2013) was used to obtain isolates from *Crataegus* sp. leaves infected with *Gymnosporangium* sp. (MT254) and *Dryopteris erythrosora* (SA444) while strain RK86 was isolated from watermelon skin. Cultures were maintained on potato dextrose agar (PDA; 39 g/L, Livonia, Michigan) slants at 4 C for short-term storage and in 40% glycerol vials at -80 C for long-term storage. Cultures of strains of the new species were dried and deposited in the Kriebel Herbarium (PUL) at Purdue University. Live cultures were also deposited at the Westerdijk Fungal Biodiversity Institute (CBS) and the Fungal Biodiversity Center and Agricultural Research Service (NRRL).

#### 3.2.3.2 *Morphological and physiological studies*

Colony and cell morphology were analyzed by culturing strains on yeast malt agar (YMA, Difco, Franklin Lakes, New Jersey), YM broth (YM broth, Difco) and Corn Meal Agar (CMA, Difco) for seven days at 25 C. Among the macro-morphological characteristics recorded were surface, form, texture, elevation and margin. Cell morphology was studied using a compound microscope OLYMPUS BH-2 (Olympus, Japan) under phase-contrast microscopy. Pictures of cells were taken by using OLYMPUS SC30 camera and the images were analyzed with the Olympus cells Sens Entry 1.14 software. A total of 20 cells was measured in width and length determine average cell dimensions. Assimilation of carbon compounds, growth in vitamin free-media and fermentation tests were performed in liquid media while assimilation of nitrogen compounds and growth on high osmotic conditions were performed in solid media according to Kurtzman et al. (2011). The ability of strains to grow on different carbon sources was assessed by using a Yeast Identification Test Panel (Biolog Inc., Hayward, California) as performed in Kijpornyongpan and Aime (2017).

### 3.2.3.3 DNA extraction, sequencing and phylogenetic studies

DNA extraction was made from fresh cultures using the Promega Wizard genomic DNA purification kit (Promega, Madison, WI). Sequences of the internal transcribed spacer (ITS) barcode region (nuclear rDNA ITS1-5.8S-ITS2) were amplified with primers ITS1F (Gardes and Bruns 1993) and ITS4 (White et al. 1990a); the D1–D2 domains of the nuc 28S rDNA (28S) with the primers LR0R/LR5 (Vilgalys and Hester 1990); the nuc 18S rDNA (18S) with primers NS1/NS4 and NS3/NS8 (White et al. 1990a) for all strains stored in the Aime collection. Finally, RNA polymerase II subunit 2, *rpb2* and cytochrome b (*cytb*) were amplified with primers 5F/6R1 and 6F/7CR (Liu et al. 1999) and E1M4/E2Mr3 (Biswas et al. 2001), respectively for strains of the new species. PCR programs for amplification of ribosomal genes are described in section 2.3.4. Protein-coding genes were amplified by using the following programs. For the *rpb2* we used the same PCR programs used in section 3.3.3. For the *cytb*, an initial denaturation step at 94 C during 2 min, followed by 35 cycles at 94 C for 30 s, annealing temperature 50 C for 30 s, 72 C for 1 min and a final extension step at 72 C for 10 min. PCR products were separated in a 1% agarose gel and sent for sequencing at GENEWIZ (South Plainfield, New Jersey). Sequences were edited, aligned and concatenated using GENEIOUS 9.1.2 (Biomatters, Auckland, New Zealand); GenBank accession numbers of sequences used in this study are listed in Table 3.4. The dataset consisted of the nuc 18S, ITS, nuclear 28S region and the protein-coding genes for the *rpb2* and the *cytb* from type strains of species in *Occultifur*, *Halobasidium* and *Cystobasidium* from previous studies. The ITS and 28S sequences of MT254, SA444 and RK86 were used to run a BLASTN search against the NCBI GenBank database, sequences of closely related accessions were included. The genus *Symmetrospora* was used as outgroup (Wang et al. 2015a). Sequences were aligned with the MAFFT V 7.222 program (Katoh et al. 2002) using the L-INS-I algorithm. For aligned sequences of each locus, ambiguously aligned regions were removed with Gblocks using the less stringent selection option (Talavera and Castresana 2007). Lastly, alignments were concatenated using GENEIOUS 9.1.2. (Biomatters, Auckland, New Zealand). The GTR GAMMA-I model was selected as the substitution model for the 5-gene region alignment according to PARTITIONFINDER2 based on the Akaike Information Criterion (AIC). Phylogenetic reconstruction was performed using Maximum Likelihood (ML) followed by 1000 bootstrap replicates using GENEIOUS 9.1.2. Bootstrap proportions (BP) are reported below. Bayesian inference (BI) was performed using

MRBAYES 3.2.6 (Huelsenbeck and Ronquist 2012) with a GTR model, nts:6, rates=invgamma according and five million generations. The first 25% of trees were discarded as Burn-in.

### 3.2.4 Results

#### 3.2.4.1 Phylogenetic studies

The multi-locus phylogeny was reconstructed using a dataset consisting of 4031 nucleotide positions. One species was delimited: *Halobasidium umbonatum* sp. nov. (MT254) (Figure 3.4). Among the sequences that are closely related to *H. umbonatum* are KC966072 from an environmental study in arctic soil, LM644065 isolated from *Arrhenatherum elatius* in Germany, JQ320370 from an unidentified plant in China, JF706656 isolated from flowers of an unidentified plant in Korea, U65613 isolated from *Chimonobambusa marmorea* in China and LT602889 isolated from *Arabidopsis phylloplane* in Finland (Yan et al 2013, Timling et al. 2014, Yurkov et al. 2015, Wang et al. 2016). Accessions that appear closely related to *H. xiangyangense* are KY986543 and EU678949 isolated from skin scales and a unidentified source in Brazil, respectively, LC272869 from seawater in Korea, and KT819328 isolated from seaweed in New Zealand, while FJ238089, FJ238090, FJ238091 and FJ865356 were all isolated from a solar saltern in Korea (Table 3.4) (Spader et al. 2017, Chin et al. 2017, Francis et al. 2016).

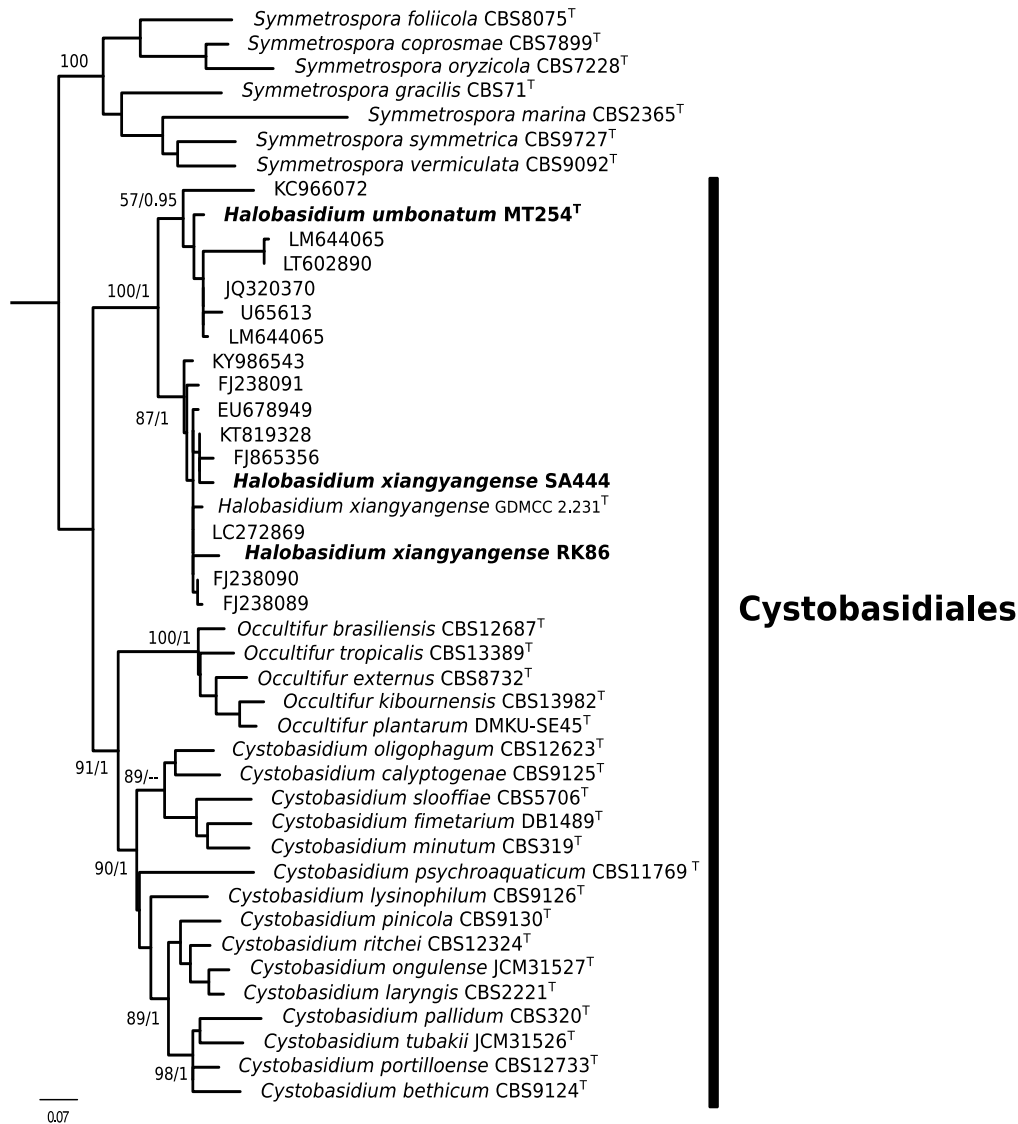

Figure 3.4 Phylogenetic reconstruction of the Cystobasidiales inferred from concatenated sequences of ITS, D1–D2 domains of nuclear 28S, nuclear 18S rDNA, *rpb2* and *cytb* using maximum likelihood. New species and strains that are new reports for western hemisphere are indicated in bold. Posterior probability (PP > 0.7) and bootstrap support (BP > 50%) values are shown above nodes. ns: not supported. Tree is midpoint rooted. Scale bar equals expected number of substitutions per site. Strain number is listed in front of the taxon name. <sup>T</sup> denotes type species strain.

### 3.2.5 Taxonomy

***Halobasidium umbonatum*** P. P. Parra & Aime, sp. nov.

FIGS. 3.5A, 3.5C

Mycobank: MB 831221

*Typification:* UNITED STATES. INDIANA: Tippecanoe County, West Lafayette, Purdue University, West Lafayette Campus, front side of Whistler Agricultural Research Building. Collected from *Crataegus* sp. leaves infected with *Gymnosporangium* sp. 29 of August 2013. *M. Toome MT254*. (Holotype preserved as dried inert cells at PUL: F24085). Ex-type cultures CBS 16090 = NRRL- 63998. GenBank: ITS = MK990658, D1–D2 domains of nuc 28S rDNA = MK990685, nuc 18S rDNA = MK990639.

*Etymology:* *umbonatum* = Referring to the umbonate elevation of colony when cultured on YMA.

*Description:* After 7 days at 25 C on YM agar colonies are pink/light coral (0ac619), glistening and butyrous in texture. Colony form is circular with entire margin and umbonate elevation. Cells occur singly or in parent-bud pairs and reproduce asexually by monopolar budding. In YM broth (YM broth, Difco) after 7 days, cells are subglobose to ellipsoidal ( $2.2\text{--}3.3 \times 3.5\text{--}4.6$ ). On CMA agar, colonies are dark pink in color (0ac611), neither true nor pseudohyphae are formed. Ballistoconidia are not produced on CMA.

Fermentation is absent. Growth is observed at 25 C and 30 C. When cultured on media containing agar (2%), yeast extract (1%) and supplemented either with 50% glucose, 10% NaCl colonies were observed but no colonies were formed when media was supplemented with 16% NaCl. Growth on vitamin free media is positive. Assimilation of  $\alpha$ -D-glucose, D-gluconic acid, , mentiobiose, D-glucuronate, inositol, DL-lactate, lactose, 1,2-propanediol is positive. Assimilation is slow on D-galacturonate, methanol and weak on 1,2-propanediol + xylose, 2-keto D-gluconate,  $\alpha$ -D-lactose + xylose, inulin, cellobiose,  $\alpha$ -D-glucose,  $\beta$ -Me-D-glucoside, adonitol, arbutin, bromosuccinic acid, D-melezitose, D-mannitol, D-arabinose, dextrin, dextrin + xylose, D-arabitol, L-aspartic acid, L-malic acid, D-galactose, D-galactose + xylose, D-glucuronic acid + xylose, D-melibiose + xylose, D-sorbitol, D-xylose, fumaric acid, gentiobiose, turanose, L-sorbose, m-inositol + xylose, glycerol, L-arabinose, Me-succinate + xylose, L-glutamic acid, Nac-D-glucosamine, L-sorbose, maltitol, NAc-L-glutamic acid, maltose, palatinose, sucrose and trehalose. Nitrogen assimilation is positive on L-lysine-HCl, D-glucosamine, D-tryptophan, KNO<sub>3</sub> (w), cadaverine-HCl (w) and imidazole (w) (Table 3.5).

*Notes: Halobasidium umbonatum* MT254<sup>T</sup> is morphologically undistinguishable from its sister species *H. xiangyangense* strain GDMCC2.2.31<sup>T</sup>, but there are several differences in their assimilation profiles. Assimilation is positive for DL-lactate, methanol (slow), lactose, D-glucosamine (weak), inositol while is negative in *H. xiangyangense* strain GDMCC2.2.31<sup>T</sup>. Sequence divergence with strain GDMCC2.2.31<sup>T</sup> is 1.6% (2.2/506 bp) and 1.2% (7/575). When *H. umbonatum* sequences are compared with *H. xiangyangense* for the other strains of *H. xiangyangense* strain SA444 the difference is 1.6% (8/506 bp), 1.5% (9/575), 15.1% (96/962) and 8.8% (35/429), for the ITS, 28S, *rpb2* and *cytb* respectively.

Figure 3.5 Colony and cell morphology. **A. C.** *Halobasidium umbonatum* MT254<sup>T</sup>. **B. D.** *H. xiangyangense* SA444. Bars: 5 μm. A, B, and C, D, were grown on YMA and YMB, respectively, for seven days at room temperature.

Table 3.4 List of taxa and accession numbers used in this study

### 3.2.6 Discussion

In this study, we describe a new species in the genus *Halobasidium*. The asexual stage of *Halobasidium* species share several characteristics with other species in the Cystobasidiales such as pink to orange colonies and ellipsoidal cells that occur singly or in parent-bud pairs (Figure 3.5A, 3.5C). The absence of pseudohyphae formation is another shared characteristic with species in most of the class. It is not possible to differentiate species in *Halobasidium* from species in *Cystobasidium* or *Occultifur* morphologically, but it is possible to identify strains based on the 28S region. When a five-gene phylogeny using the 18S, ITS, 28S, *rpb2* and *cytb* was built, these genera are separated into three highly supported monophyletic genera (Figure 3.4). According to Hibbett et al. (2011) an average of 1200 species were identified per year from 2001 to 2011. Although the number of described species is rising with the help of molecular techniques, there are several taxa of fungi that receive less attention due to their cryptic nature in ecosystems or just because their role in nature is still unknown.

During the last ten years, only ten species in the Cystobasidiales have been formally described; nonetheless, there are still several lineages represented by strains that have been reported in research papers but that remain undescribed. One example is evidenced by at least 12 accessions deposited in the NCBI that appear closely related to *Halobasidium* but remained undescribed until recently (Guo et al. 2019). From these reports, the first collection was made in 1997 from bamboo (Zhang et al. 1997), meaning that strains belonging to the now described *Halobasidium* were found 21 years ago but did not elicit a formal description and proposal for a long time. These records of sequences related to *Halobasidium* indicate that its geographic distribution is not limited to China or the United States, but it also can be found in Finland, Germany and Korea. The habitats in which sister taxa have been isolated range from plants to extreme niches such as arctic soil or salterns which are characterized by hypersaline waters (>3.5% NaCl). This coincides with the fact that both species of *Halobasidium* can grow on media containing 10% NaCl, as observed in other species of the Cystobasidiales such as *Occultifur externus*, *C. calyptogenae*, *C. minutum*, *C. lysinophillum*, *C. oligophagum* and *C. tubakii* (Nagahama et al. 2003, Tsuji et al. 2016). With the discovery of the ability of species in *Halobasidium* to grow under high osmotic conditions (media containing 50% glucose) we identified other habitats in which species in the Cystobasidiales can be found. The only xerotolerant species in the Cystobasidiomycetes previously reported is *Cystobasidium pallidum*.

## CHAPTER 4. TAXONOMIC REVISION AND THE EVOLUTION OF HABITAT PREFERENCE IN THE CYSTOBASIDIOMYCETES

### 4.1 Introduction

The Cystobasidiomycetes (Basidiomycota: Pucciniomycotina) consists of 13 genera and over 70 species, currently placed in five orders: Buckleyzymales, Cystobasidiales, Erythrobasidiales, Naohideales and Sakaguchiales (Aime et al. 2006, 2014, Bauer et al. 2006, Zhao et al. 2017). Species belonging to the Cystobasidiomycetes have been isolated from different habitats, ranging from aquatic environments, soil, insects, mammals and plants. Several species have been found in association with or parasitizing other fungi, also known as mycoparasitism. Different interactions that occur in nature between organisms are not well documented or studied; instead the habitat preference that refers to where the fungus was found, could then reflect a preference towards a certain life strategy or substrate (Chaverri and Samuels 2011) either parasitic, saprotrophic, endophytic, etc. The early-diverging position of *Naohidea sebaceae* (a mycoparasite) within the class and the occurrence of mycoparasitism and host associations found in several lineages of the Cystobasidiomycetes has led to the hypothesis that the Cystobasidiomycetes may have arisen from nanometer-fusion mycoparasites (Bauer 2004). Hence the possibility of mycoparasitism or close association with other fungi being an ancestral character should not be neglected.

Mycoparasitism, which consists in the direct physical contact between two fungi is one of the several antagonistic interactions observed in fungi. Antagonism can also occur through the production of toxic compounds and other agents against competing organisms, through the competition for nutrients or by stimulating host defense mechanisms (Karlsson et al. 2015, Narayanasamy 2013). Mycoparasitism and the production of toxic compounds have been reported in the Cystobasidiomycetes; out of these two phenomena, the less studied is the production of toxic compounds. This type of antagonism that mainly occurs between the yeast stage of the fungi and other organisms was first described in *Saccharomyces cerevisiae* (Bevan and Makeower 1963) and has been more extensively studied in ascomycetous yeasts. In Basidiomycota only 50 yeast species have been reported as producers of these compounds, in the Cystobasidiomycetes only two species, *Cystobasidium pallidum* and *Hasegawazyma lactosa*, have been reported to produce toxic compounds (Klassen et al. 2017).

Another type of antagonism; mycoparasitism, involves direct physical interaction. Mycoparasitism, is associated with sexual states and has been reported in species of *Cystobasidium*, *Naohidea*, *Cyphobasidium* and *Occultifur*. In the Naohideales, the species *Naohidea sebacea* has been found in association with plants such as *Fraxinus* sp. and maple (Berk and Broome 1971), but also has been reported as a parasite of old stromata of *Botryosphaeria dothidea* (Piatek 2002), *Botryiodiplodia* sp., *Botryosphaeria quercuum* (Mcnabb 1965), on a sphaeriaceous fungus (Olive, 1947) and also observed on pycnidia of a *Phialophorophoma*-like fungus (Bandoni 1973). In the Cystobasidiales, the hyphal stage of *Cystobasidium fimetarium* has been found growing on dung with other ascomycetous fungi like *Thelebolus crustaceus* and *Lasiobolus equinus*, on which it is presumed to be mycoparasitic (Roberts 1999). Similarly, *C. sebaceum* was found growing on remnants of an old *Sebacina* sp. on decaying wood (Martin 1939). In the genus *Occultifur*, *O. corticiorum* was isolated from a basidiocarp of *Tylospora fibrillosa* (Roberts 1997), *O. internus* was isolated from *Dacrymyces stillatus* (Olive 1954), *O. rivoirei* was found parasitizing *Hyphodontia arguta* (Trichies 2016) and *O. lumbricifer* has been described as an intrahymenial parasite on *Hyphodontia subalutacea* (Roberts 2001). Lastly, *Cyphobasidium hypogymniicola* and *Cyphobasidium usneicola* have been found in association with lichens on several species of *Usnea*, *Bryoria* and another 50 genera (Diederich 1996, 2007, Spribille et al. 2016, Millanes et al. 2015).

Fungal association of species in the Cystobasidiomycetes have not only been reported during the hyphal stage; other species such as *Erythrobasidium hasegawianum* have been isolated from an old culture of beer yeast, *Cystobasidium psychroaquaticum* has been found in association with the lichen *Cladonia pocillum* (Zhang et al. 2015) and *Hasegawazyma lactosa* has been isolated from fungus gardens of *Atta texana* presumably antagonizing other microbes (Rodrigues et al. 2009). Additionally, sequences from environmental samplings have evidenced the presence of Cystobasidiomycetes in *Hemileia vastatrix* pustules in coffee leaves (James et al. 2016).

It should be considered that several species in the Cystobasidiales found in association with other fungi have been described only from morphological characters. Among these species are *C. sebaceum* (Martin 1939) while in *Occultifur* there are five species: *O. corticiorum* (Roberts 1997); *O. rivoirei* (Trichies 2016); *O. internus* (Olive 1954); and *O. lumbricifer* (Roberts 2001). As stated by Crous et al. (2014), it is of vital importance for fungal taxonomy the application of generic names based on DNA sequence data when possible and not only on morphology and ecology, although it is not always possible. Such importance is demonstrated in *Occultifur*, for which the

taxonomic affiliation of the type species *O. internus* is unknown leading to a taxonomic uncertainty for the genus (for more details about the genus see Chapter 1).

Due to the lack of molecular data for the type species *O. internus*, the species *O. externus* for which molecular data are available is not only the most studied species in the genus, but also has been used as the reference species for the genus in most of the phylogenetic studies (Sampaio et al. 1999, Wang et al. 2015b). In this chapter, for the first time, we use molecular data to establish the phylogenetic affiliation of *O. internus* and we present evidence of mycoparasitism as a life strategy in another lineage in the Cystobasidiomycetes that remained unknown until now. Additionally, we made phylogenetic reconstructions using the ITS and 28S gene regions to classify sequences from strains and environmental sampling available in the NCBI that are conspecific to extant species of the Cystobasidiomycetes and were not classified before or were not classified correctly. In this way, we can identify host associations that remained unknown for these species and include them in further analyses. Lastly, a seven-locus phylogenetic reconstruction of the class and ancestral state reconstruction analyses were performed to study the evolution of habitat preference of species in the class and to test whether the Cystobasidiomycetes could have arisen from a mycoparasitic ancestor.

## 4.2 Materials and Methods

### 4.2.1 *Specimens and strains*

Herbarium specimens KM068754 and KM094773, were acquired from the Royal Botanical Gardens, KEW, and brought to the Aime lab for DNA extraction. Also, cultures of strains belonging to eight genera of the Cystobasidiomycetes collected in different countries were included in the Aime Lab Collection (See section 2.2.1) for further analyses.

### 4.2.2 *DNA extraction, PCR and sequencing*

DNA extraction from specimens KM68754 and KM94773 along with strains of Cystobasidiomycetes in the Aime Lab collection was performed using the Promega Wizard genomic DNA purification kit (Promega, Madison, Wisconsin). The ITS, D1–D2 domains of the nuclear 28S rDNA (28S) and *tefl* (for *O. internus* specimens) were amplified by PCR following the conditions used in section 2.2.4. PCR products were separated in a 1% agarose gel and sent to GENEWIZ (South Plainfield, New Jersey) for direct sequencing. Sequences were edited in

GENEIOUS 9.1.2 (Biomatters, Auckland, New Zealand). Sequences of newly described species in previous studies (Chapter 2 and Chapter 3) and sequences from strains of the Cystobasidiomycetes in the Aime Lab collection were included in the analyses.

#### 4.2.3 *Phylogenetic analyses*

Sequences for the ITS1-5.8S-ITS2 (ITS), the D1–D2 domains of nuclear 28S rDNA (28S), nuclear 18S rDNA (18S), and portions of the *tef1*, *rpb1*, *rpb2* and *cytb* genes were retrieved from the NCBI repository for the type strain of all extant species. Also, sequences of newly described species in the previous chapters were included. The ITS, nuclear 28S and nuclear 18S sequences of type strains of extant species in the class were searched against the NCBI GenBank database using BLASTn; the most closely related accessions and sequences of strains of the Cystobasidiomycetes in the Aime Lab Collection were used to build single-gene phylogenies for species delimitation. Duplicates of sequences in each dataset were removed using the remove duplicates built-in function in GENEIOUS 9.1.2 (Biomatters, Auckland, New Zealand). Phylogenetic reconstructions were made using: 1) Seven concatenated gene regions for extant species in the class. *Sterigmatomyces hyphaenes* was used for outgroup purposes (Wang et al. 2015b); 2) Three gene regions including the ITS, 28S and 18S to resolve the phylogenetic position of *Occultifur internus*; and 3) Single-gene region phylogenies for species in each genus of the Cystobasidiomycetes using ITS, 28S and 18S sequences. GenBank accession numbers for sequences used to build a resolved phylogeny of the Cystobasidiomycetes are provided in Table 4.1, while accession numbers for single-gene phylogenies used in the species delimitation are provided in Table A1. Sequences used in all phylogenies were aligned with MAFFT 7.222 (Katoh et al. 2017) using the L-INS-I algorithm. Alignments of the seven- and four-gene regions were concatenated in GENEIOUS 9.1.2 (Biomatters, Auckland, New Zealand). The GTR GAMMA-I model was selected as the substitution model for the seven- and four-gene phylogenies according to PARTITIONFINDER2 based on the Akaike Information Criterion (AIC). Phylogenetic reconstruction using seven- and four- gene regions were performed using Maximum Likelihood (ML) followed by 1000 bootstrap replicates, and Bayesian inference (BI) was performed using MRBAYES 3.2.6 (Huelsenbeck and Ronquist 2012) with a GTR, an INVGAMMA model and five million generations. For species delimitation using single-gene regions only ML analysis was performed. Both, ML and BI analyses were run using the packages available in the Purdue University super computer cluster.

#### 4.2.4 *Species delimitation and host association*

We used a phylogenetic species concept (PSC) to delimit species based either on the ITS, 28S or 18S region. When sequences of multiple loci were available for one strain, their phylogenetic placement was determined according to genealogical concordance for phylogenetic species recognition based on individual gene phylogenies (GCSR). The purpose of this strategy was to identify more accurately the phylogenetic placement of sequences reported in the NCBI, strains in the Aime Lab Collection and to include in our datasets all the sequences available for the species in the Cystobasidiomycetes. In summary, we built phylogenies of the ITS, 28S and 18S sequences for every genus in the class. Once each accession from the NCBI was assigned to a species, information about location or country, isolation source (substrate) and whether the sequence corresponds to a culture collection or environmental sampling was recorded.

#### 4.2.5 *Ancestral character reconstruction and host preference reconstruction*

According to Chaverri and Samuels (2013), the habitat preference specifically refers to where the fungus was isolated and this host association could reflect a preference for a particular life strategy. Based on this concept we used the substrate of isolation as a proxy to investigate the trophic strategy of species in the class. We grouped these associations into five categories: Animals (A), aquatic (B), fungi (C), plants (D) or decaying organic matter (E). The ancestral character reconstruction to study the evolution of the host preference of species in the Cystobasidiomycetes was made using BayesTraits v3.0.1 with two approaches: 1) Maximum Likelihood (ML) and 2) Markov Chain Monte Carlo (MCMC). As one species can have more than one host association, we used a multistate approach. The ML ancestral character reconstruction was run using a multistate approach and default parameters. For the MCMC approach we used a reversible-jump MCMC, burn-in of 10 000, sample frequency: 1 000, and 1 000 000 iterations. Posterior probability for each possible ancestral state was calculated for both ML and MCMC by averaging across post-burn-in estimates of 1000 trees of each node.

### 4.3 Results

#### 4.3.1 Phylogenetic studies: A resolved phylogeny of the *Cystobasidiomycetes*

Individual alignments for type strains of species in the *Cystobasidiomycetes* consisted of 593 (ITS), 606 (28S), 1 690 (18S), 1003 (*tef1*), 787 (*rpb1*), 974 (*rpb2*) and 432 (*cytb*) nucleotide positions after exclusion of ambiguously aligned positions. We obtained sequences for the ITS, 28S and the *tef1* from specimens KM68754 and KM94773 of *Occultifur internus* and included them in our seven-gene region phylogeny. To determine the phylogenetic placement of *O. internus*, datasets consisting of three (18S, ITS and 28S) and seven (18S, ITS, 28S and *tef1*, *rpb1*, *rpb2* and *cytb*) combined gene regions comprising 2 889 and 6 085 nucleotide sites, respectively, were used. Based on the phylogenetic reconstructions using these datasets, we established the non-monophyletic nature of *Occultifur*. In our analysis, *O. internus* appears as congeneric to species in *Microsporomyces* using the two datasets and appears as sister species of *Microsporomyces bloemfonteinensis* (Figure 4.1). Based on the results from our phylogenetic reconstructions and aiming to clarify the phylogenetic affiliations of species such as *O. internus* for which molecular data is presented for the first time, we propose several taxonomic changes in the *Cystobasidiomycetes*, in particular in *Occultifur* and *Microsporomyces* (See section 4.4). As *O. internus* is the type species for the genus, species in *Microsporomyces* should be transferred to *Occultifur*. Consequently, the former *Occultifur* should be renamed.

Once the phylogenetic relationships in the *Cystobasidiomycetes* were resolved (Figure 4.2), we proceeded to perform species delimitation based on the PSC and GCSR. We assigned sequences available in the NCBI as well as sequences generated in this study to extant species in the class. In this chapter we do not only classify sequences (listed as uncultured fungus or that were not classified correctly), but also, we identified new associations, substrates, habitats and locations in which members of the *Cystobasidiomycetes* were not reported in the past.

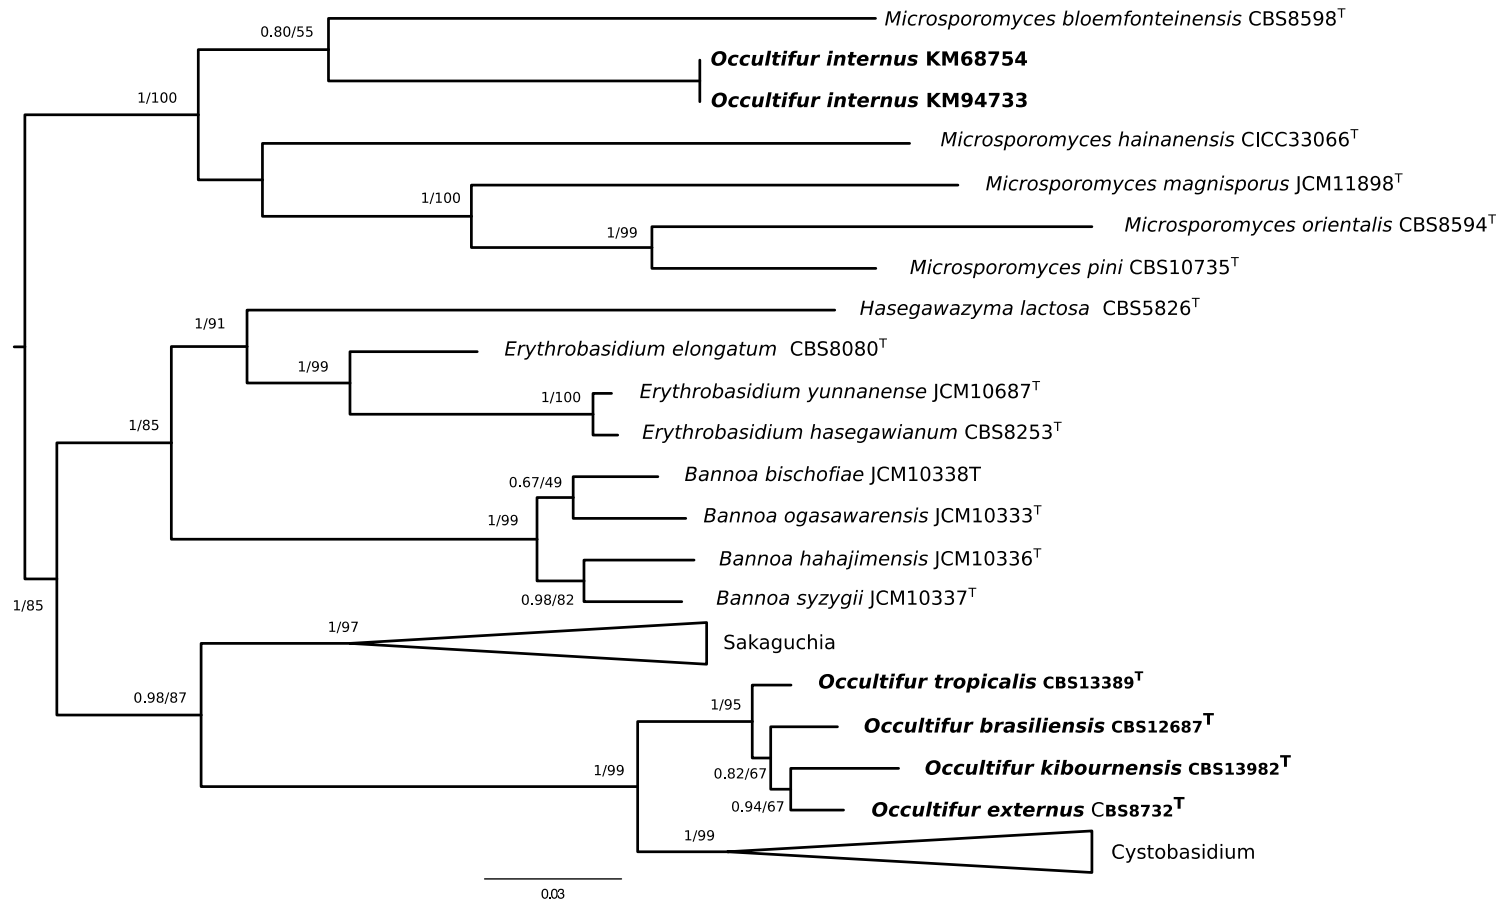

Figure 4.1 Phylogenetic placement of *Occultifur internus* inferred from combined sequences of ITS, D1–D2 domains of nuc 28S and nuc 18S rDNA using maximum likelihood and Bayesian analysis. Species in *Occultifur* are indicated in bold. Posterior Probability (PP>0.7) and Bootstrap support (BP>50%) values are shown above nodes. Bar 0.03 substitutions per nucleotide position. <sup>T</sup> denotes type species strain.

Figure 4.2 Phylogenetic reconstruction of the Cystobasidiomycetes inferred from combined sequences of ITS, D1–D2 domains of nuc 28S, nuc 18S rDNA, *tef1*, *rpb1*, *rpb2* and *cytb* using maximum likelihood and Bayesian analysis. Posterior Probability (PP>0.7) and Bootstrap support (BP>50%) values are shown above nodes. ns: not supported. Bar 0.04 substitutions per nucleotide position. <sup>T</sup> denotes type species strain.

Note: ----- : No sequence available. Accession numbers in bold were generated in the present study. Other accession numbers were retrieved from the NCBI. <sup>T</sup> denotes type species strain. Type strain species for each genus appears in bold.

#### 4.3.2 *Species delimitation, host associations and geographic distribution*

A total of 794 sequences were available from both cultures and environmental samplings in the Cystobasidiomycetes retrieved from the NCBI. The database also included sequences generated from strains in the Aime Lab. Out of the 794 sequences, 608 (76.6%) were assigned to one of the extant species in the class, while 186 (23.4%) sequences remained unclassified because they appeared as independent evolutionary lineages and may represent new species. Sequences of the Cystobasidiomycetes have been isolated from all over the world, being Asia where more occurrences have been reported (394), while North America and Europe showed similar numbers, 121 and 141 respectively. In Oceania and South America, the number of occurrences is lower with 40 and 52 respectively; followed by Africa and Antarctica with 24 and 27 occurrences. Lastly, the lowest number of occurrences are for Central America and the Caribbean with 1 and 3 respectively.

The country with the higher number of occurrences is China with 156 in 26 species belonging to the genera *Buckleyzyma*, *Cystobasidium*, *Erythrobasidium*, *Halobasidium*, *Hasegawazyma*, *Occultifur*, *Pseudoccultifur*, *Sakaguchia* and *Symmetrospora*; i.e., in nine out of the 13 genera of the Cystobasidiomycetes. The second country with the highest number is the USA with 98 occurrences in 30 species belonging to the 9 genera listed above and *Cyrenella*. In Europe, Portugal is the country with the highest number of occurrences (37) of the Cystobasidiomycetes in 13 species of eight genera.

At the genus-level, the highest number of occurrences are in *Symmetrospora* (190), *Cystobasidium* (149) and *Erythrobasidium* (87), with species isolated from the all over the world. Contrarily, the monotypic genera *Cyrenella* has only one occurrence in Brazil, Germany, Portugal and the USA respectively. The genus *Hasegawazyma* has been mostly reported from Asia and only one occurrence in the USA.

From the phylogenies built with the 18S, ITS and 28S gene regions it was possible to delimit species and identify new host associations that were not reported until today. For example, new species of *Bannoa* that have been documented in Chapter 2 not only represent an increase in the number of known species for the genus but also, a larger geographic distribution. Additionally, other strains (MCA7643, MCA7637, MCA7670, MCA7672, MCA7674) that are congeneric to *Bannoa* have been isolated from Vanuatu and may represent new species. In *Buckleyzyma*, for the species *B. aurantiaca* our analyses indicate an association with the gut of insects in the family

Chrysomelidae and Staphylinidae. This species has also been isolated from *Atta texana* in which it is presumed to play an antagonistic role against other microorganisms. Both associations had never been reported. In terms of geographic distribution, *B. aurantiaca* in the present study is reported for the first time in Austria, Canada, Portugal and Finland (Prillinger et al. 1996, Rodrigues et al. 2009, Stefani et al. 2016). New associations of *Buckleyzyma salicina* also have been identified from an unclassified sequence on *Vitis vinifera*, while strain P117 from the Aime lab has been isolated from *Pinus nigra*. Both reports are the two only known of this species for the United States.

*Cystobasidium calyptogenae* has been reported from Japan, India and Taiwan, however, several sequences from an uncultured fungus isolated from seawater have been reported from China which is a new report for this species. Also, sequences classified as *Cystobasidium* sp. “classicola” that appeared conspecific to *C. calyptogenae* have been isolated from Thailand and Canada, that along with the strain SA628 from the Aime Lab Collection are the first reports of the species in the western hemisphere. For *Cystobasidium laryngis* we have identified uncultured and unclassified sequences that were isolated from a coprophilous fungus in Norway, this is not only the first time that this species is reported to be associated with fungi but also is the first report of the species from Norway. Also, in the current study we show for the first time that *Cystobasidium minutum* strain MCA4210, reported from the United States isolated from the mycangia of *Sirex* wasp. Other strains such as MCA7620 and MCA7407 were isolated from *Lygodium* sp.; MCA7423 and MCA7611 from Vanuatu are the first report for this location. Despite *C. minutum* has been already reported in China from *Camellia sinensis*, in this study we identified environmental sequences that were isolated from seawater, a habitat from which this species had not been reported.

*Cystobasidium ongulense*, previously only known from Antarctica, based on our analyses this species has a wider geographic distribution. Collection P107 from the Aime Lab isolated from *Rubus* sp., TAR415 from *Dryopteris erythrosora* and MCA715 from an unknown plant were obtained from the USA, Iceland and Canada, respectively. Also accessions KU145512 and MF062208 isolated from Chile and China that were classified as *C. laryngis*, are actually conspecific to *C. ongulense*. Other sequences from environmental sampling, KP314689 and KR004864, that appear as *C. ongulense* were isolated from a coprophilous fungus (Zhang et al. 2015) and lichen, respectively, in Norway. *Cystobasidium psychroaquaticum* comprised only two classified sequences, the type strain from Russia from *Chamaedaphne calyculata* and one

additional strain from Bulgaria from a Springtail Sminthuridae feeding on fungus. Other unclassified sequences, that are conspecific to *C. psychroaquaticum*, were isolated from the lichen *Cladonia pocillum* and from a coprophilous fungus in Norway. Association with fungi was never reported previously. Also, we report the strain *MT096* isolated from *Dryopteris erythrosora* in the USA, the first report of this species in the American continent. For *C. slooffiae* new geographic distributions include, the Republic of Korea from seawater culture (LC272874), also seawater in China (KU163884), while in Finland *C. slooffiae* has been isolated from indoor environments (AB726571), in Japan from soil samples (AB726571) and in the USA, from leaves, stem and kernels of *Zea mays*. Lastly, strain SA515, stored in the Aime Lab collection, along with accessions EF505775 and KF800332, are the only reports for this species in North America (Table A1).

In *Erythrobasidium*, we identified sequences of from environmental sampling labeled as “Uncultured fungus” isolated from *Hemileia vastatrix* pustules in Coffee leaves in Mexico (James et al. 2016). Accession KT328766 was identified in the study conducted by James et al (2016) as *Symmetrospora oryzae*, however, our analyses placed this sequence as conspecific to *Erythrobasidium yunnanense*. Similarly, we identified a sequence from an uncultured fungus (KT328645) conspecific to *E. elongatum* cohabiting *Hemileia vastatrix* pustules, this time in Puerto Rico (James et al. 2016). Lastly, despite the type species of *Erythrobasidium hasegawianum* being isolated from an old culture of yeast beer, it has been traditionally found in association with plants in Portugal (e.g., EU002836, EU002836, EU002836) and lake water in China (KT239097, KT345331, KT345330). We identified from the Aime Lab Collection, the strain MCA6865 as *E. hasegawianum*; this strain was isolated from an unidentified leaf infected by the rust fungus *Puccinia coronata* in Russia. Also, we identified two sequences (AM901803, KF815655) of uncultured fungus conspecific to *E. hasegawianum* that were isolated from house dust and air sampling in Finland and Slovakia, respectively. Both are new reports for *E. hasegawianum* in these countries.

*Occultifur internus* has been reported previously from the fungi *Peniophora* sp., *Hyphoderma argillaceum* and Dacrymycetales hosts; however, because of the new sequences of *O. internus* generated in this study, it was possible to identify environmental sequences that remained unclassified that are conspecific to *O. internus*. Sequences KU948766 and KU948779 were isolated from the lichens *Cladonia multiformis* and *Cetraria ericetorum*, respectively, in the United States. These findings suggest that this mycoparasitic species is not only found on fungi

but also that it may be a parasite of lichens. Also, accession KF274414 was isolated from *Picea abies* represents the first non-fungal host association and the first report of *O. internus* in Finland. Lastly, other unclassified *Symmetrospora* sequences from environmental sampling and cultures were assigned to *Symmetrospora coprosmae*, these sequences represent the first report of this species in countries such as in Belgium where accession KP100170 was obtained from *Aphis spiraecola*, while in Slovakia, France, Thailand and Czech Republic, *S. coprosmae* has been reported from overwintering grape (KT933355), air sampling (HG008765), corn phylloplane (HG008765), and roots of *Neottia ovata*. One additional sequence was obtained in Mexico from *Hemileia vastatrix* pustules by James et al. (2016 (See Chapter 1). A compilation of host and substrates in which extant species in the Cystobasidiomycetes have been isolated is shown in Table 4.2. Detailed data of the accession number, substrate, host associations and geographic distribution for every sequence used the species delimitation for host association studies in this chapter are listed in Table A1.

Table 4.2 Ecological characteristics, geographic distribution for extant of the Cystobasidiomycetes from sequences available in the NCBI. Formation or ring and pellicle is also listed.

### 4.3.3 Host preference evolution in the *Cystobasidiomycetes*

In the present study, we show a seven-gene phylogeny including 72 taxa in the *Cystobasidiomycetes*, of which 66 are described species and four taxa that are in process of formal description in the Aime Lab. Also, we present information regarding the habitat preference of species in one or several categories defined: Animals, fungi, plants, aquatic habitat or decaying organic matter (Figure 4.3). Based in our analyses, there is not an evident pattern of specialization towards a particular substrate or habitat. For example, a species can be found in association with animals or plants, or even isolated from aquatic environments, fungi, or decaying organic matter. Also, single species have been found in association with plants of different families or insects that are phylogenetically distant (e.g., *Erythrobasidium yunnanense*, *Bucklezyzma aurantiaca*, see Table 4.2).

By using the seven-gene region phylogeny and the known host association for species in the class according to five categories (Animals, aquatic, fungi, plants or decaying organic matter), we reconstructed 19 nodes for the habitat preference of the most recent common ancestor (MRCA) in the *Cystobasidiomycetes*. Our ancestral character reconstruction using the MCMC (Marco Chain Monte Carlo) shows that the host association of the MRCA of the *Cystobasidiomycetes* is uncertain, however it is likely that the MRCA was associated with either plants (Figure 4.3, Node 1, PP: 0.43), fungi (Node 1, PP: 0.31) or decaying organic matter (Node 1, PP: 0.19). Preference for a habitat was gained several times in the class, for example: The MRCA of the *Erythrobasidiales* appears to have a habitat preference for decaying organic matter (Node 8, PP: 0.82) but there was a gain in habitat preference towards plants for the MRCA of the *Erythrobasidium* and *Bannoa* (Node 11, PP: 0.78). Also, a gain in habitat preference toward plants is observed in the MRCA of *Bucklezyzma* (Node 4, PP: 0.93) and *Symmetrospora* (Node 7, PP: 0.97). However, species in these genera have also been found in association with decaying organic matter, animals and fungi. In the *Cystobasidiales*, habitat preferences were gained in the evolution of the order, from plants (Node 14, PP: 0.55) to animals in the MRCA of *Cystobasidium* (Node 18, PP: 0.67) even when several species in the genus also have been found in association with plants and fungi. Lastly, the MRCA of *Halobasidium* gained habitat preference towards plants and aquatic environments (Node 19, PP: 0.45). Multiple changes in habitat preference have been reported in the evolution of the *Cystobasidiomycetes*, it seems like the preference for habitat or host association with fungi is apparently lost. Our analyses also show that habitat preference

towards fungi in some MRCAs has been lost in recent lineages (e.g. Node 2, 3, 5, 8). We obtained similar reconstructions for the ancestral character when the analysis was performed using the ML approach.

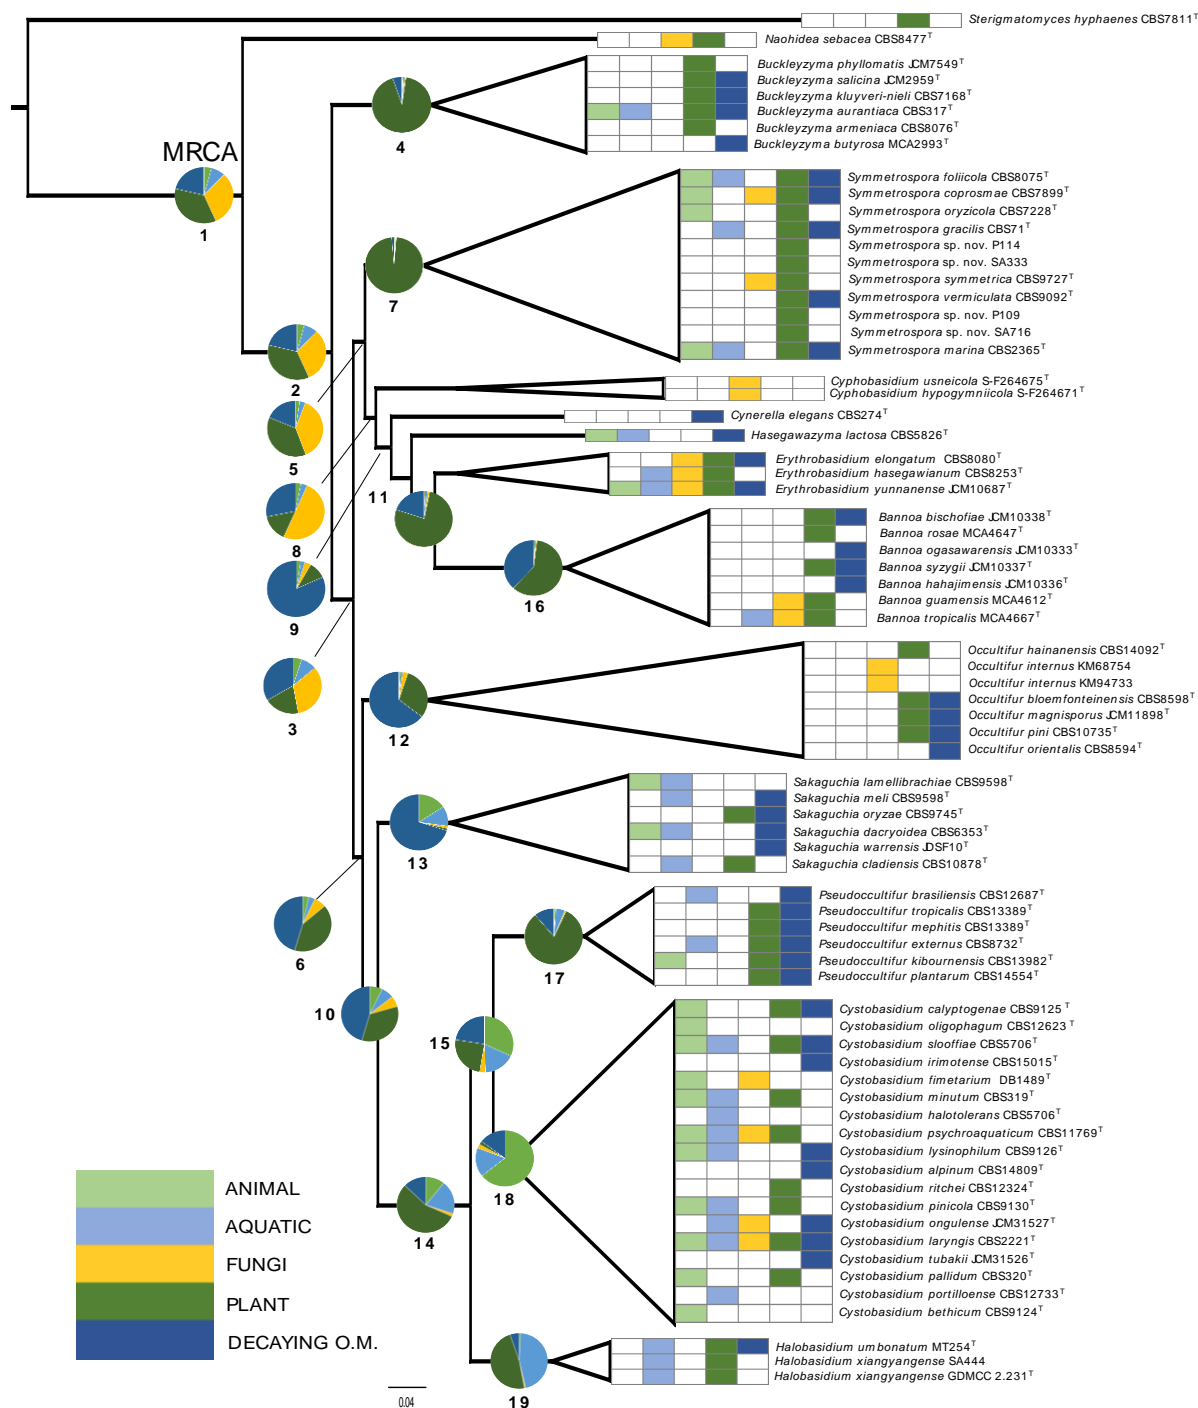

Figure 4.3 Ancestral character reconstruction using MCMC (Markov Chain Monte Carlo). Colors represent the different categories of habitat preference of species in the Cystobasidiomycetes. Backbone was built based on the ITS, D1–D2 domains of nuc 28S, nuc 18S rDNA, *tefl*, *rpb1*, *rpb2* and *cytb* using ML.

#### 4.4 Taxonomy

***Occultifur*** Oberw. 1990. Reports of the Tottori Mycological Institute 28: 119 (1990).

MB#25570

Type species: *Occultifur internus* (L.S. Olive) Oberw. 1990.

Basionym: *Platyglea peniophorae* var. *interna* L.S. Olive, Bulletin of the Torrey Botanical Club 81: 331 (1954)

The description is that of *Platyglea peniophorae* var. *interna* L.S. Olive 1954.

Basionym: *Occultifur kilbournensis* Kurtzman & Robnett, *Antonie van Leeuwenhoek* 107 (5): 1325 (2015) [MB#811259]

***Pseudocultifur lumbricifer*** (P. Roberts) P.P. Parra & Aime, comb. nov.

MycoBank: 371011

Basionym: *Occultifur lumbricifer* (P. Roberts) Trichies, *Bulletin de la Société Mycologique de France* 119: 325 (2004).

≡ *Achroomyces lumbricifer* P. Roberts, *Sydowia* 53: 152 (2001).

***Pseudocultifur mephitis*** (Zalar, Šibanc & J.P. Samp.) P.P. Parra & Aime, comb. nov.

MycoBank: 818568

Basionym: *Occultifur mephitis* Zalar, Šibanc & J.P. Samp., *International Journal of Systematic and Evolutionary Microbiology*: [8] (2018).

***Pseudocultifur plantarum*** (P. Khunnamw., J.R.A. Ribeiro, Hagler, M. Takash., Sugita, Jindam. & Limtong) P.P. Parra & Aime, comb. nov.

MycoBank: 819736

Basionym: *Occultifur plantarum* P. Khunnamw., J.R.A. Ribeiro, Hagler, M. Takash., Sugita, Jindam. & Limtong, International Journal of Systematic and Evolutionary Microbiology 67 (8): 2630 (2017).

***Pseudocultifur rivoirei*** (G. Trichies) P.P. Parra & Aime, comb. nov.

MycoBank: 818646

Basionym: *Occultifur rivoirei* Trichies, Bulletin Mensuel de la Société Linnéenne de Lyon 86 (1-2): 20 (2016).

## 4.5 Discussion

The genus *Occultifur* was erected by Oberwinkler (1990) to accommodate *O. internus*, which is the type species for the genus. This species is presumed to be a mycoparasite during its hyphal stage on fungi in the Dacrymycetales (Bauer et al. 2006). The hyphal stage has never been reported in species of the former genus *Microsporomyces* and has never been found in association with other fungi. Instead, species in the genus have been mostly isolated from plants such as *Oryza sativa*, *Miscanthus floridulus* and pines trees (Pohl et al. 2011, Bai et al. 2016). The presence of a hyphal stage of *O. internus* not only suggests that other species in this lineage may be dimorphic but also indicates the occurrence of mycoparasitism in another evolutionary lineage within the Cystobasidiomycetes. Mycoparasitism as life strategy in *Pseudocultifur* requires further investigation. Despite species such as *Pseudocultifur lumbricifer* being found as an intrahymenial parasite on *Hyphodontia subalutacea* (Roberts 2001), *P. corticorum* has been isolated from *Hyphoderma praetermissum* (Roberts 1997) and *P. rivoirei* was recently described growing parasitically on *Hyphodontia arguta* (Trichies 2016), molecular data is still not available for these species. The lack of molecular data as in *O. internus* makes more difficult the task of establishing their phylogenetic affiliation and to better understand the evolution of host preferences and life strategy in this genus. The case of *O. internus* is the best example of the relevance of molecular data in fungal taxonomy, especially when the type species of a genus lacks it.

In general, the life strategy for most of the species in the class is still unknown, however, as more strains or reports from environmental samplings are available from different habitats and

substrates, it may be possible to identify the habitat preferences of species in the class and their most likely life strategy if additional efforts are invested to study these species in natural ecosystems. Additional efforts should be made to correctly classify sequences in public repositories since they are the source to identify geographic distribution and host preferences of species in the class. Despite species of the Cystobasidiomycetes have a global distribution, the number of occurrences is not uniform, for example, in Central America there is only one report, which does not mean that Cystobasidiomycetes are not distributed in this region, but it is due likely to under sampling or sampling bias. We have found that over 40% (Chapter 1) of the sequences available for the Cystobasidiomycetes were not assigned to one of the extant species in the class, making the task of studying habitat preference more demanding and more difficult to establish their possible role in nature.

The hypothesis is that closely or phylogenetically related taxa may have the same role or trait in nature because of the shared ancestor (Powell et al. 2009, Parrent et al. 2010). Nevertheless, there are some challenges in defining the life strategy of dimorphic species, since the kind of interactions a particular species may have during the yeast stage can greatly change during the hyphal stage. It is then possible that the yeast stage of a species exhibits preferences towards a habitat while these preferences switch during the hyphal stage. In our case, we based our ancestral character reconstruction mostly on host preference of the asexual stage, for this reason it is of vital importance to know the interactions that species of this class have in nature during the hyphal stage. After more information is gathered, studies like this can be revisited to draw definitive conclusions about the life strategy and host preference. According to Chaverri and Samuels (2013), most of the shifts in habitat preference are observed among organisms that are more closely related phylogenetically while interkingdom shifts are less frequent, however, in the Cystobasidiomycetes we observed interkingdom shifts in most of the lineages during the asexual stage, which means that a single species can be found either on fungi, animals or plants.

## CHAPTER 5. FINAL REMARKS AND FUTURE WORK

For over 20 years, the Aime Lab has put a huge amount of effort to understand the phylogenetic relationships among species in Basidiomycota, the phylum to which the Cystobasidiomycetes belong. Over 7800 fungal specimens collected from all over the world are stored in the Aime Lab collection and represent an invaluable resource for research purposes. Among the 80 strains of Cystobasidiomycetes in the collection, there is representation of 13 already described species and at least 10 potential new species of which six have been described in this dissertation.

We have observed from the host association studies in the fourth chapter of this dissertation, that the Cystobasidiomycetes is a very diverse class of fungi in terms of host associations with species of different kingdoms and habitats. However, for most species in the class we still do not know what kind of interactions they have and their role in nature. Additional questions regarding their reproductive biology are still unresolved. The main motivation for conducting studies on this class consisted in the potential of describing a big number of new species to science that deposited in the Aime Lab culture collection. By formally describing these species and investigating their habitat preference, their phylogenetic relationships and possible roles in nature, we could contribute to the understanding we have of the class and the possible applications they may have in agriculture or biotechnology.

In the first chapter we collected available information from the literature to make a general review of the 13 genera in the Class. We emphasized on the sexual stage of species when present, and also some of the host associations and known geographic distribution. One of the main objectives of our studies was to describe new species to science that were stored in the Aime Lab Culture collection. In Chapter 2, we described three new species, *B. guamensis*, *B. rosea* and *B. tropicalis*, raising the number of species in this genus to seven. Previously described species were all obtained from the south of Japan and just a small number of sequences had been reported from other locations. Two species-level lineages from environmental sampling may represent new species in the genus. We also reported for the first time a member of *Bannoa*, *B. tropicalis* from South America, indicating a broader geographic distribution of the genus. We also performed intercompatibility studies on ten strains of *Bannoa*. We were able to report the development of a hyphal stage when compatible strains of *B. tropicalis* were crossed and incubated in the dark in

comparison with those incubated at higher temperatures and other light:darkness regimes. Despite it is uncertain whether the hyphal stage commonly occurs in natural conditions, it is possible that this is a mechanism either to reach resources or to interact with other fungi affecting the host plant. Our data indicate that *B. tropicalis*, *B. guamensis*, and environmental isolates can be isolated from rust sori and may be co-inhabitants of this microniche during the yeast stage. Further studies should be focused to study the interactions between species of *Bannoa* and its host, in this way it would be possible to determine if there is either a parasitic or epiphytic relationship.

We also described new species in three genera of the Cystobasidiomycetes in Chapter 3 namely: *Buckleyzyma butyrosa*, *Halobasidium umbonatum* and *Sakaguchia warrensis* (Figures 3.3 and 3.5). In our phylogenetic analyses, we included available sequences in the NCBI and information from the literature to expand the range of distribution and substrates in which species of these three genera can be isolated. Also, we identified several lineages in *Sakaguchia* that may represent new species (Figure 3.2). Based on the phylogenies built in Chapter 2 and 3, it is possible to conclude, that there is still a lot of diversity to be discovered in these four genera.

The basis for understanding the evolution of traits and relationships among species consists in having the best possible taxon sampling to build the phylogenies and to include information about the ecological features of each taxon in the analysis. In the Cystobasidiomycetes, several species in *Cystobasidium* and *Occultifur* lack molecular data for which it is not possible to know with certainty their phylogenetic affiliation. This is especially important if the species for which molecular data is missing is the type species of the genus, this is the case of *Occultifur internus*. We established that *O. internus* was not conspecific to other described species in the genus. Instead, it was phylogenetically related to *Microsporomyces* (Figure 4.1). This finding led us to propose new combinations and the proposal of a new name for those species in the former *Occultifur* (See section 4.4). In this dissertation we have mentioned several times that mycoparasitism has been reported in several generic lineages in the class, but for most of the species their role in nature remains unknown. Considering this, we performed an ancestral character reconstruction to test whether mycoparasitism is ancestral. After gathering information from over 790 available reports in the NCBI and assigning them to extant species based on PSC and GCSR we identified host associations and geographic distribution that were unknown for many species in the class (Section 4.3.2). Patterns of specialization were not identified, in fact, species can have associations with species in different kingdoms during the asexual stage. As they

have not been regularly studied in nature, the occurrence of the hyphal stage and the level of specialization during this stage remains understudied.

Over 50% of the sequences available in the NCBI for species in the Cystobasidiomycetes are not or are ambiguously classified, the value behind the effort of conducting species delimitation of these sequences is to enlarge not only the host range but also their geographic distribution. In addition, our Chapter 4 highlight the importance of having a criterion for the assignation of a species (or at least genus) to a strain or sequence obtained from environmental samplings. From the ancestral character reconstruction study, we observed several changes in host preference in lineages such as *Buckleyzyma* and *Symmetrospora* and to aquatic environments in *Sakaguchia*. However, these results are not conclusive due to the bias that could exist due to the fact that plants are more commonly sampled than any other substrate, for example other fungi.

Future research in the Cystobasidiomycetes also should be focused on studying the interaction of these species with their host in natural conditions, especially, because specific growing conditions are not always replicable under laboratory conditions. In this dissertation we reported that Cystobasidiomycetes can be co-inhabitants of rust sori, lichens, and fruiting bodies of other fungi. These niches should be considered for future samplings and studies to better understand the interactions that may occur. For example, in case there is mycoparasitism of species of Cystobasidiomycetous yeast that are co-inhabiting pustules of *Hemileia vastatrix*, they could be used as a biological control alternative to fight this devastating disease.

Mycoparasitism is not the only antagonistic interactions the Cystobasidiomycetes may have in natural ecosystems, also the production of antimicrobial compounds to outcompete other microorganisms has been reported during the asexual stage. Taking advantage of the considerable amount of strains in the Aime Lab collection, we evaluated the presence of antimicrobial compounds of 54 strains. We used the following methodology: A sensitive strain was allowed to grow for 24h on media containing 0.3% yeast extract, 0.3% malt extract, 0.5% peptone, 1.0% glucose, and 2.0% agar, supplemented with 0.003% methylene blue and pH 4.2. Each strain in the Cystobasidiomycetes tested for killer activity was also incubated for 24h on Yeast Malt agar and inoculated by making a single streak on the plate containing the sensitive strain. Cultures were evaluated every 24h for 5 days for the presence of an inhibition zone with no growth. Over 900 dual cultures were made using the previously described system and we found that *Kluveromyces lactis* strain NRRL Y-6628 is weakly sensitive to substances produced by *Bannoa guamensis* strain

MCA4612. Similarly, we found that *Papiliotrema laurentii* strain MCA7145 is sensitive to *Symmetrospora coprosmae* strain MT264 (data not shown).

Lastly, the production of biofilms, that is defined as the association of yeast cells or other microorganisms to improve their performance (Mittelbach and Vannette 2017) (e.g., as a defense mechanism against toxic compounds), has not been studied in a wider context in the Cystobasidiomycetes. However, we have taken the first step and we collected available information from the literature; also we performed experiments in our laboratory to test which strains from our collection produce a ring (that can be interpreted as a biofilm) when cultured in liquid media (yeast extract 50 mg/l, casa amino acid mg/l and 1% glucose) (Table 4.2). Despite we did not have the opportunity to study the biofilms and how relevant they are in the defense mechanism of the asexual stage in nature we understand the importance of documenting these preliminary results and the need for further research in this topic in yeast fungi, especially in the Cystobasidiomycetes.

## APPENDIX

Table A.1 Accession number and host association for sequences of the Cystobasidiomycetes used in species delimitation.

**Note:** C: Cultured fungus: Strain in private or public culture collection. UC: Uncultured fungus: Environmental sampling S: Specimen. Type strain species for each genus appears in bold. Accession numbers in bold were generated in The Aime Lab. Other accession numbers were retrieved from the NCBI.

Figure A 1 Phylogenetic reconstruction for *Bannoa* inferred from combined sequences of ITS, D1–D2 domains of nuclear 28S and nuclear 18S rDNA using ML and BI analysis. New species indicated in bold. Posterior Probability (PP > 0.7) and Bootstrap support (BP > 50%) values are shown above nodes. ns: not supported. Bar 0.01 substitutions per nucleotide position. <sup>T</sup> denotes type species strain.

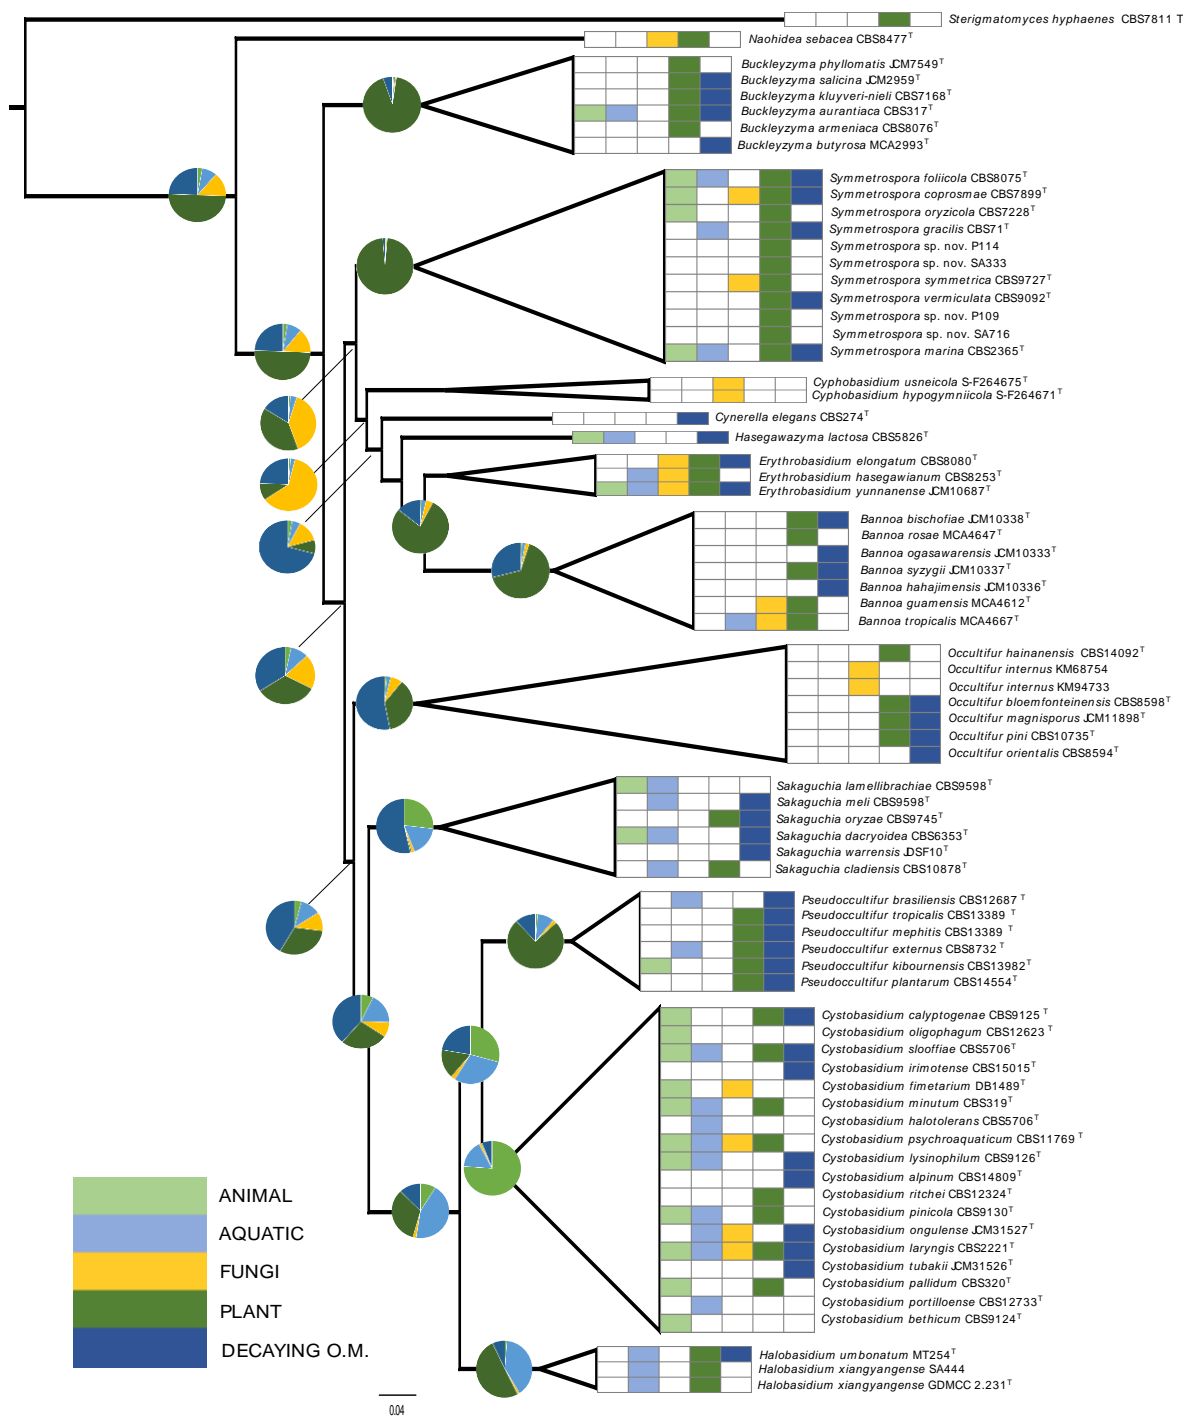

Figure A 2 Ancestral character reconstruction using ML (Maximum Likelihood). Colors represent the different categories of habitat preference of species in the Cystobasidiomycetes. Backbone was built based on the ITS, D1–D2 domains of nuclear 28S, nuclear 18S rDNA, *tef1*, *rpb1*, *rpb2* and *cytb* using ML.

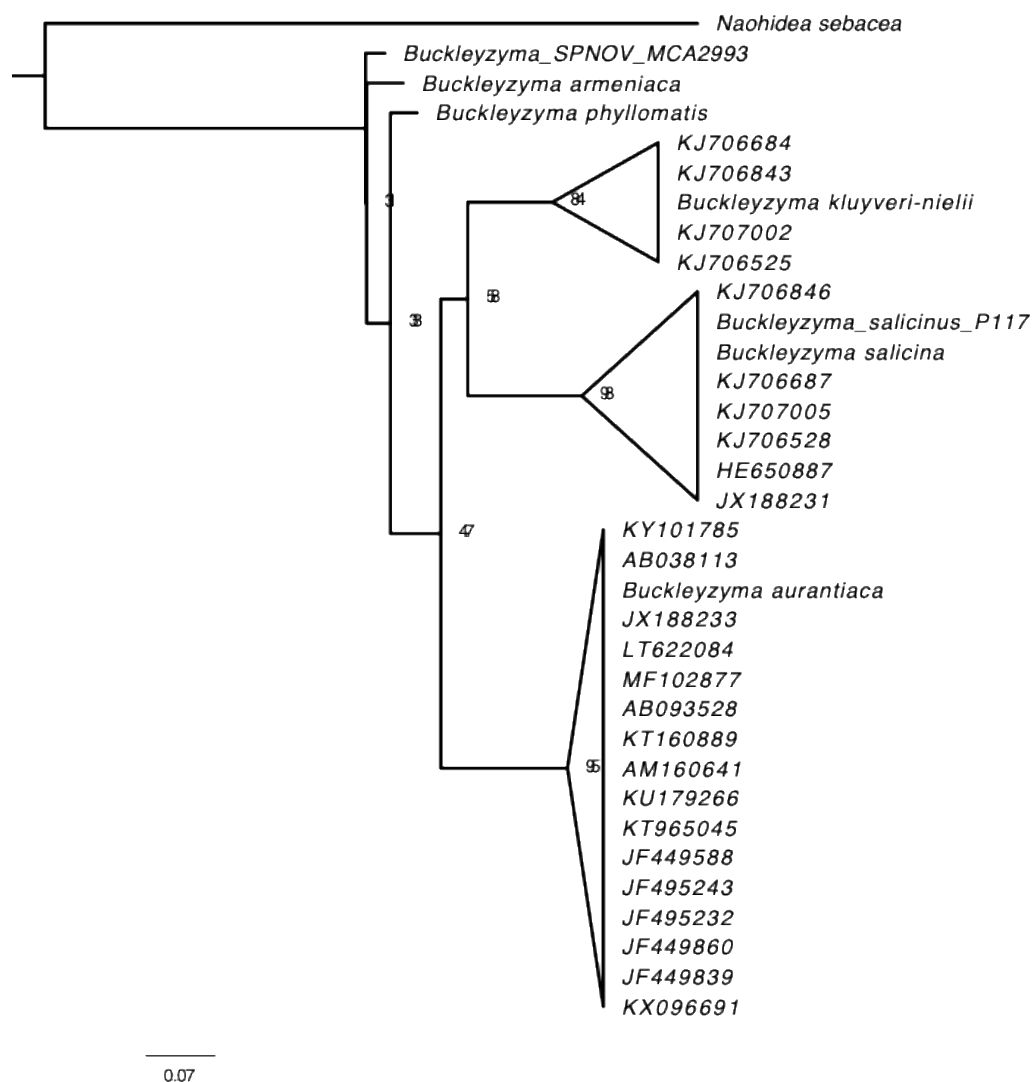

Figure A 3 Phylogenetic reconstruction for *Buckleyzyma* inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

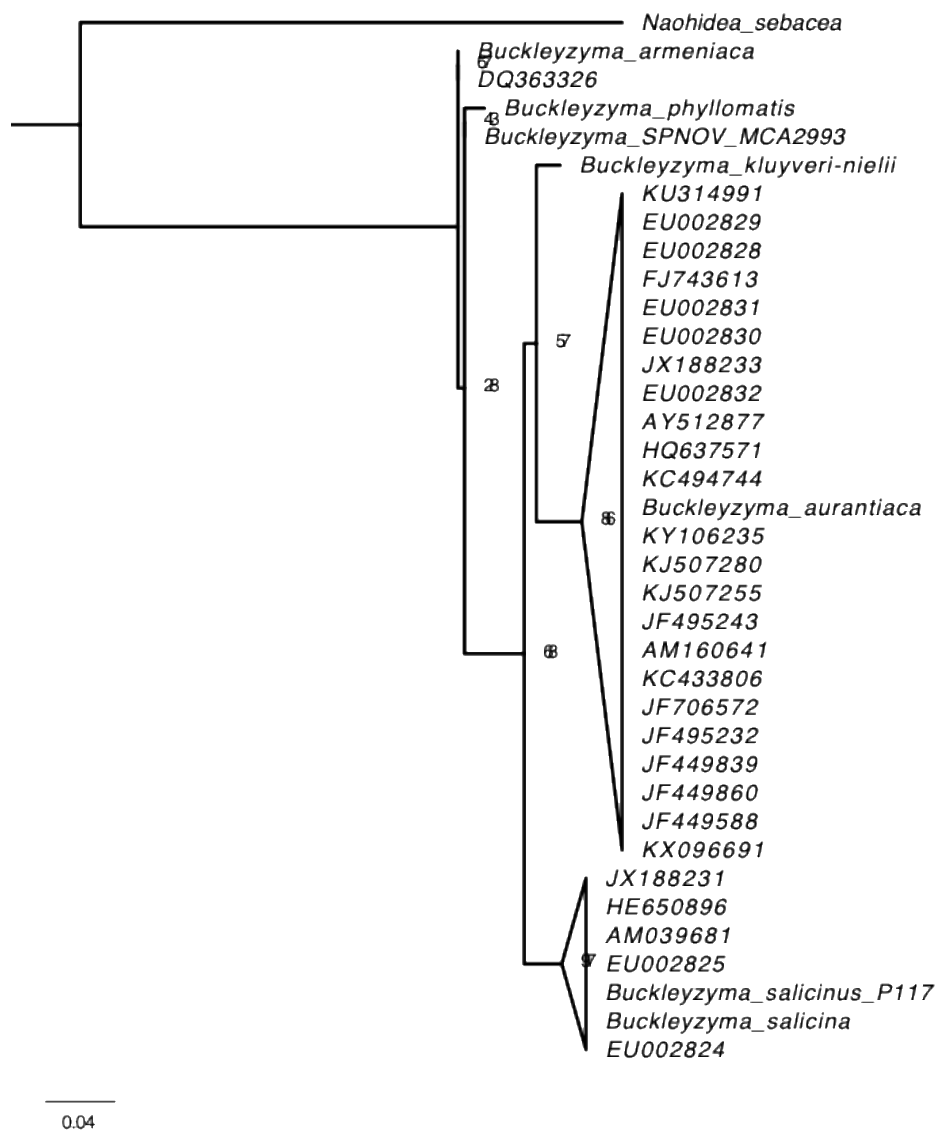

Figure A 4 Phylogenetic reconstruction for *Buckleyzyma* inferred from the D1–D2 domains of nuclear 28S using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

Figure A 5 Phylogenetic reconstruction of the Cystobasidiales inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree.

Figure A 5 Continued Phylogenetic reconstruction of the Cystobasidiales inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree.

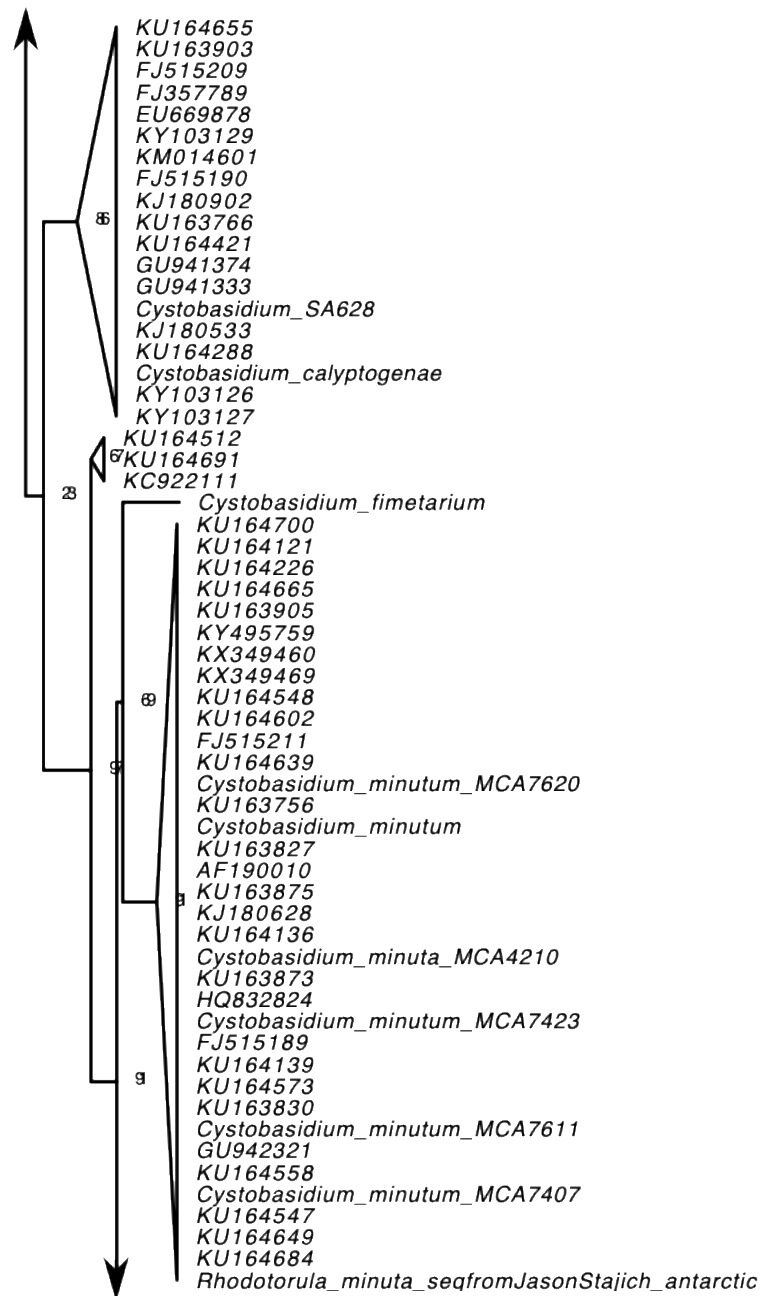

Figure A 5 Continued Phylogenetic reconstruction of the Cystobasidiales inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree.

Figure A 5 Continued Phylogenetic reconstruction of the Cystobasidiales inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

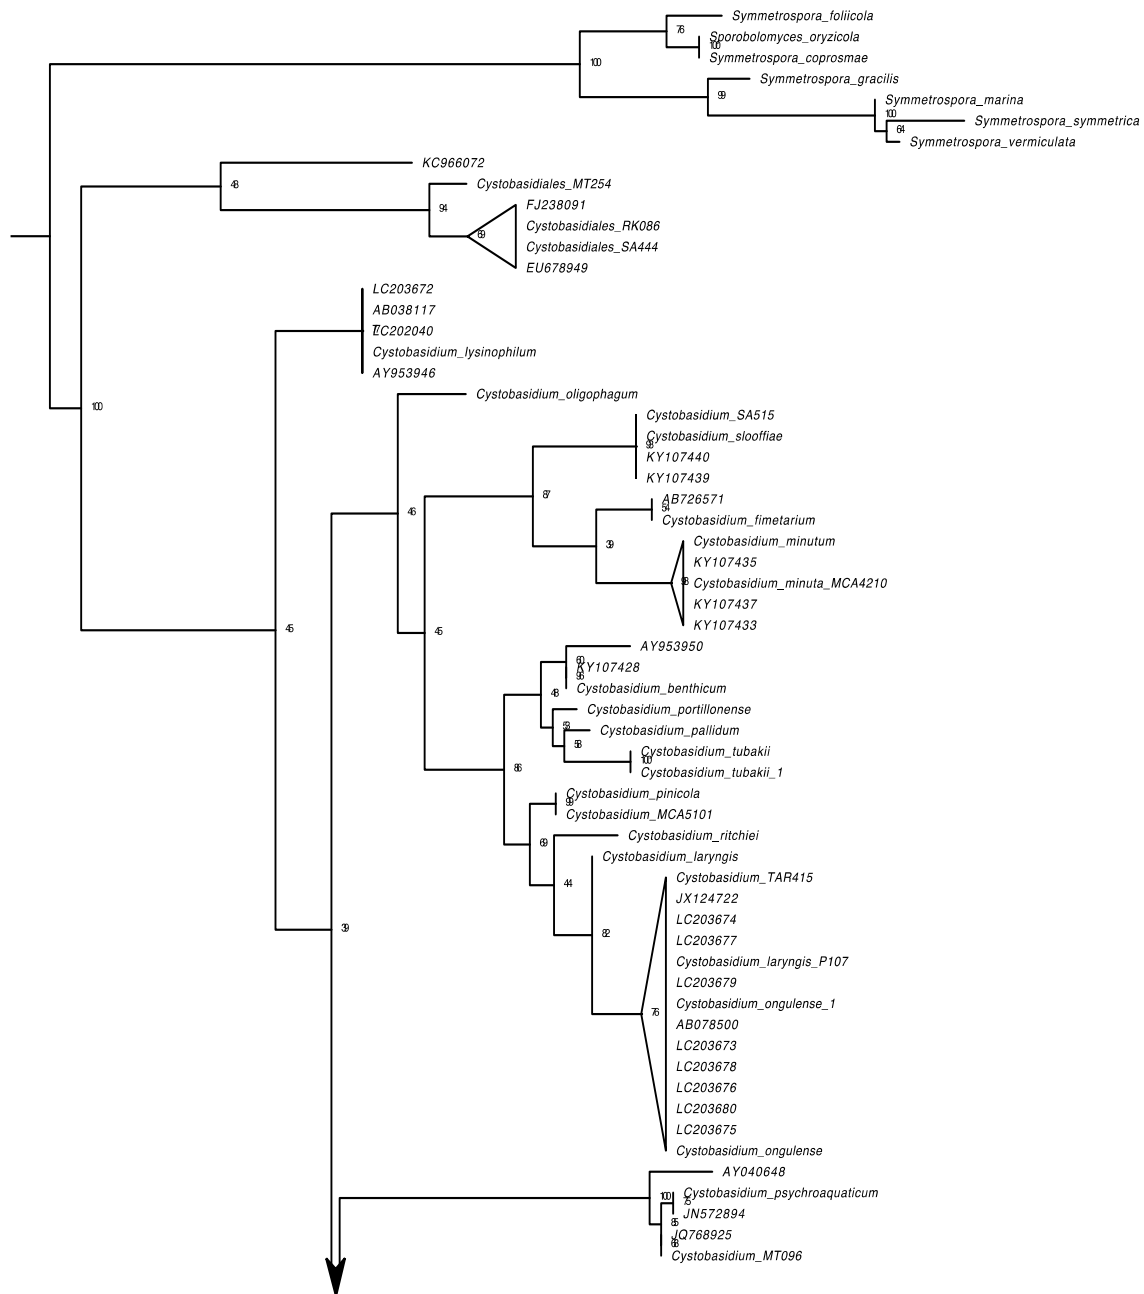

Figure A 6 Phylogenetic reconstruction of the Cystobasidiales inferred from the D1–D2 domains of nuclear 28S using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree.

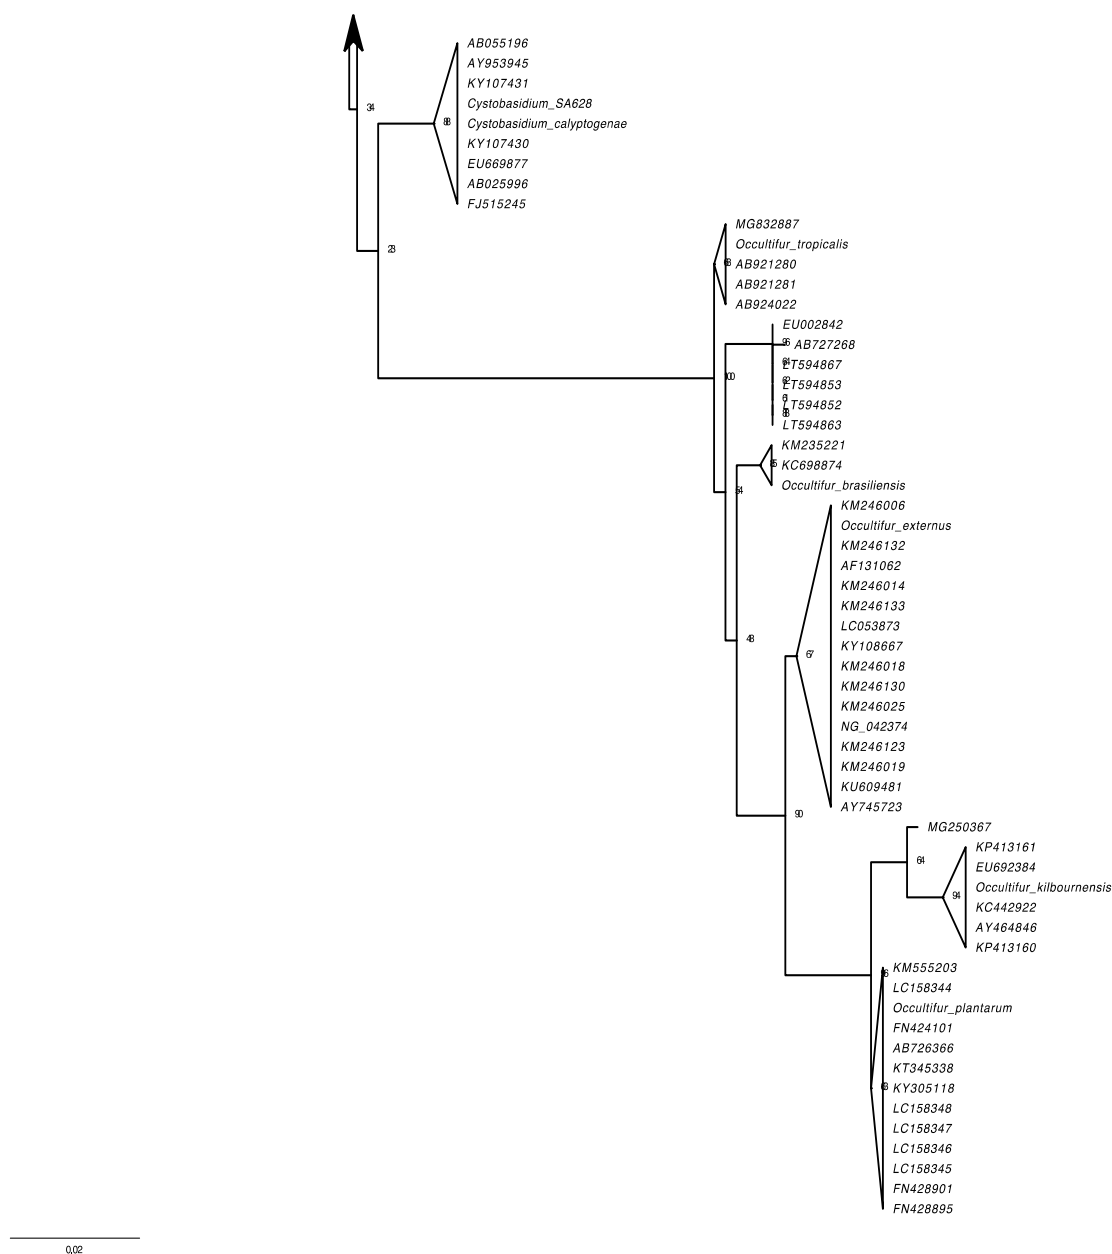

Figure A 6 Continued Phylogenetic reconstruction of the Cystobasidiales inferred from the D1–D2 domains of nuclear 28S using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

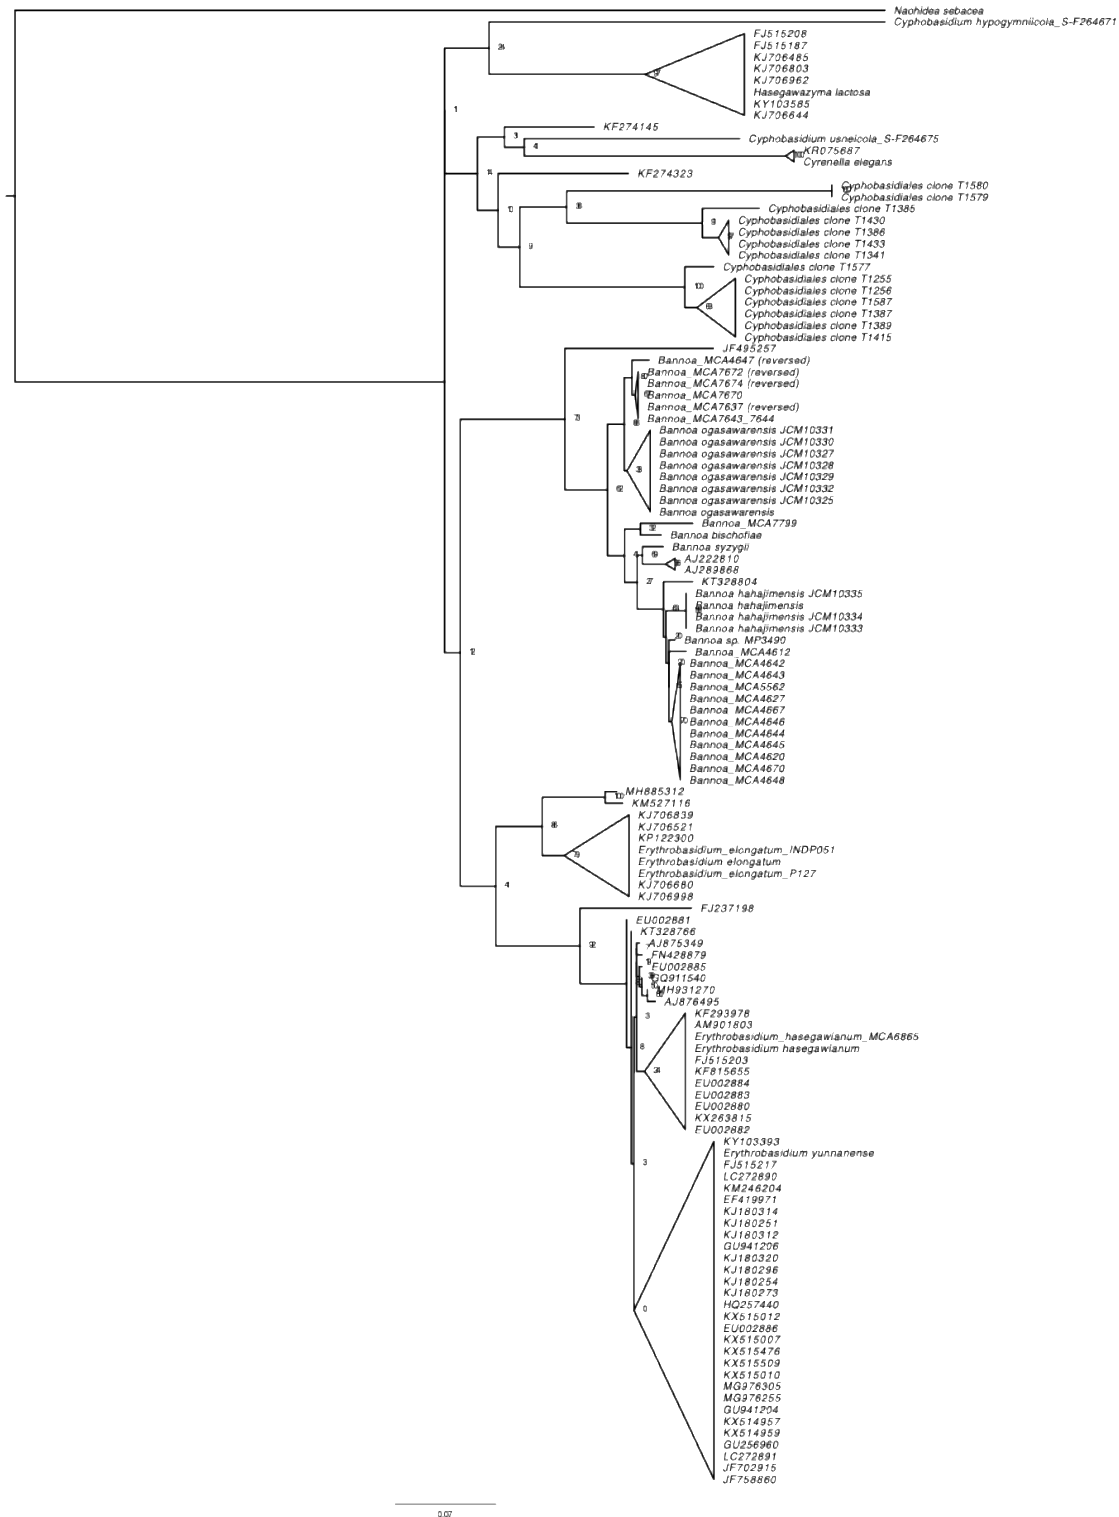

Figure A 7 Phylogenetic reconstruction of the Erythrobasidiales and the genus *Cyphobasidium* inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

Figure A 8 Phylogenetic reconstruction of the Erythrobasidiales and the genus *Cyphobasidium* inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

Figure A 9 Phylogenetic reconstruction of *Microsporomyces* inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

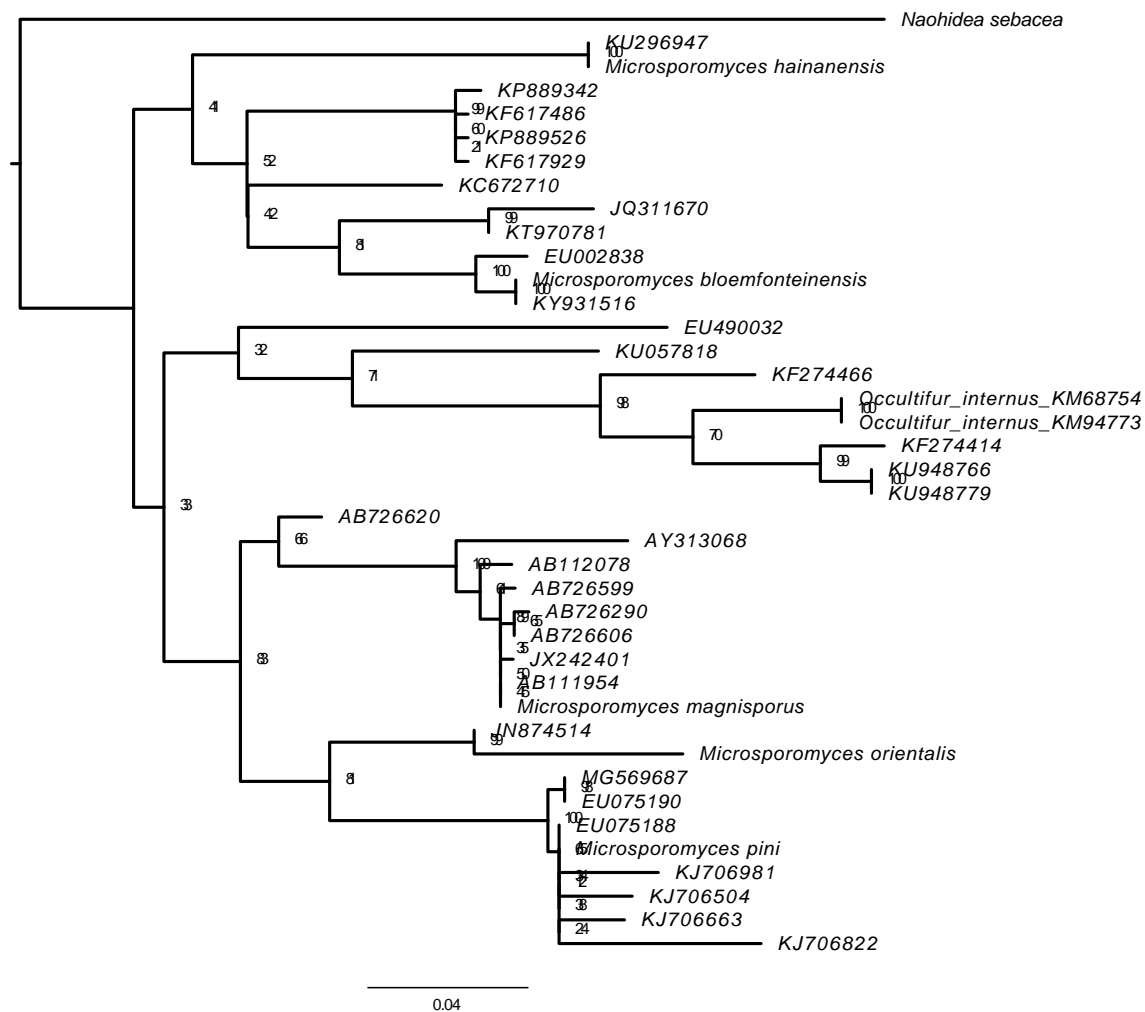

Figure A 10 Phylogenetic reconstruction of *Microsporomyces* inferred from the D1–D2 domains of nuclear 28S using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

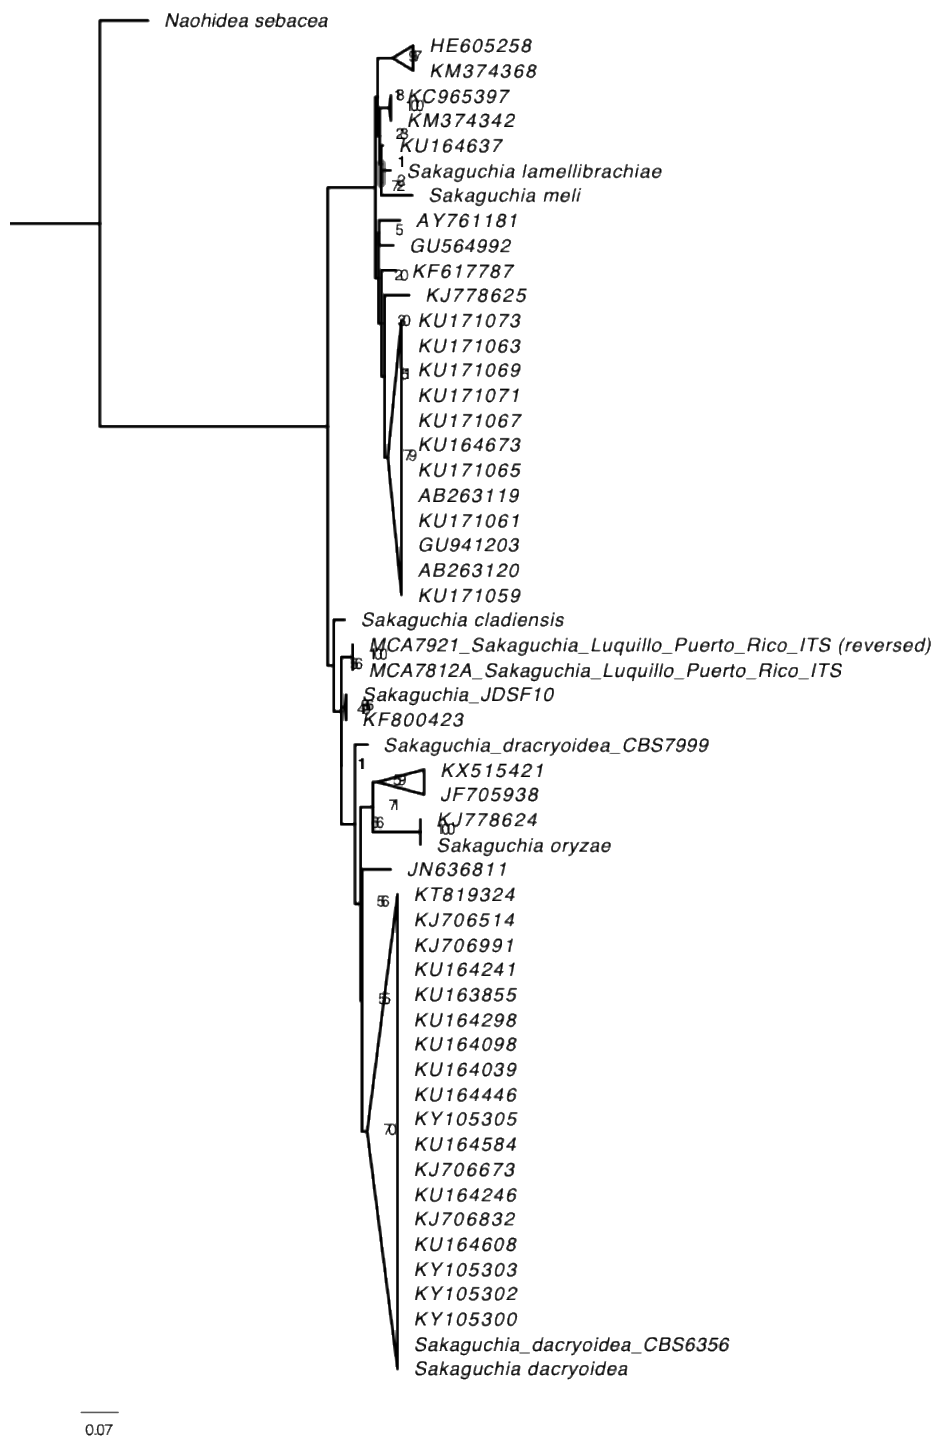

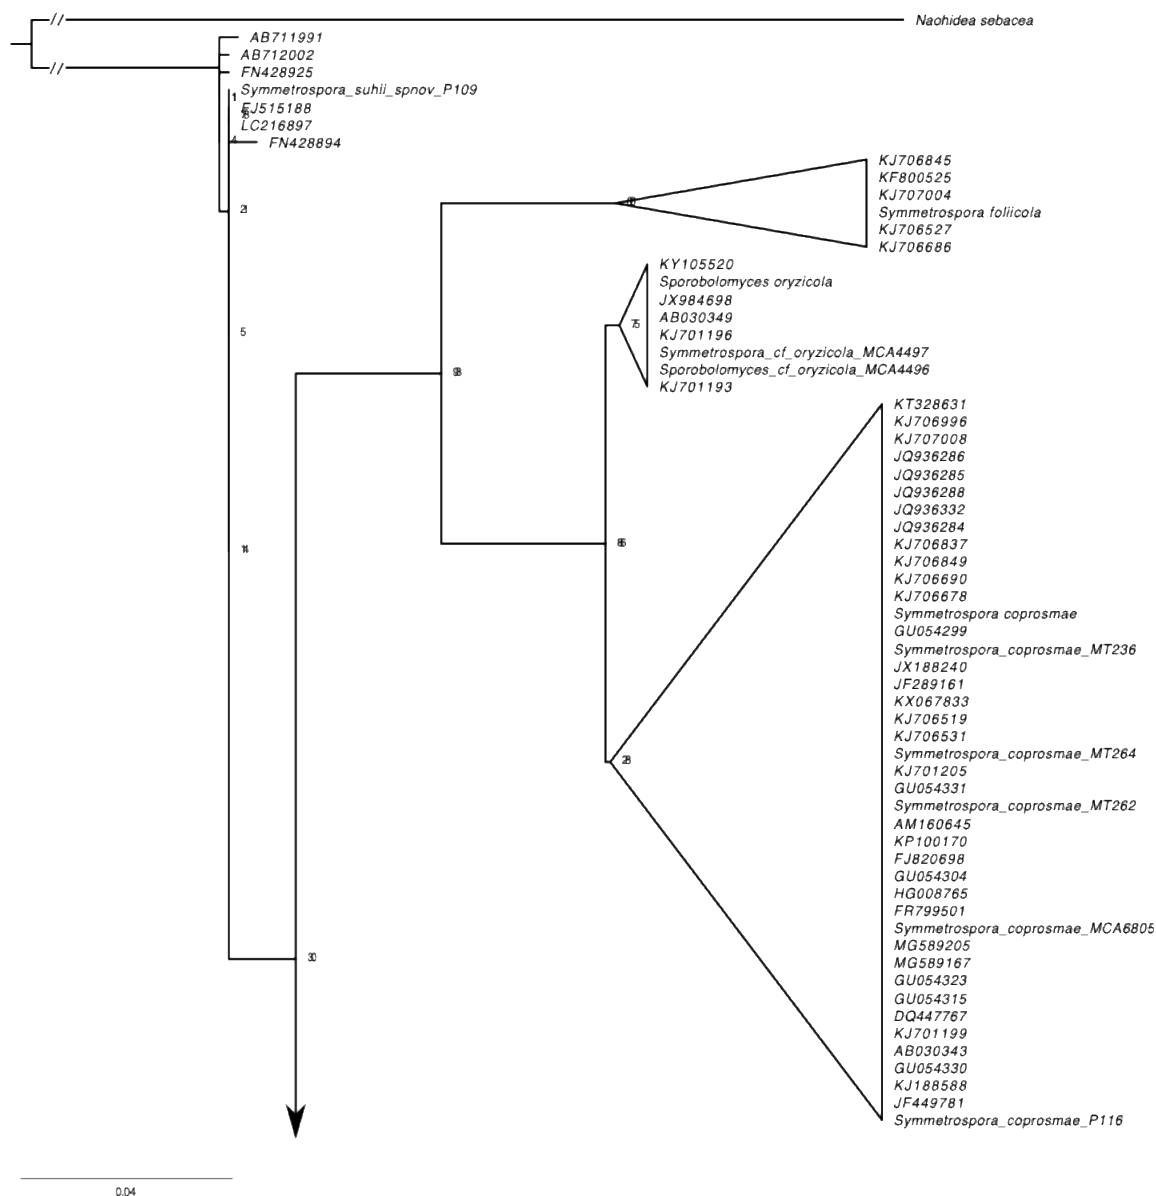

Figure A 11 Phylogenetic reconstruction of *Sakaguchia* inferred from the ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

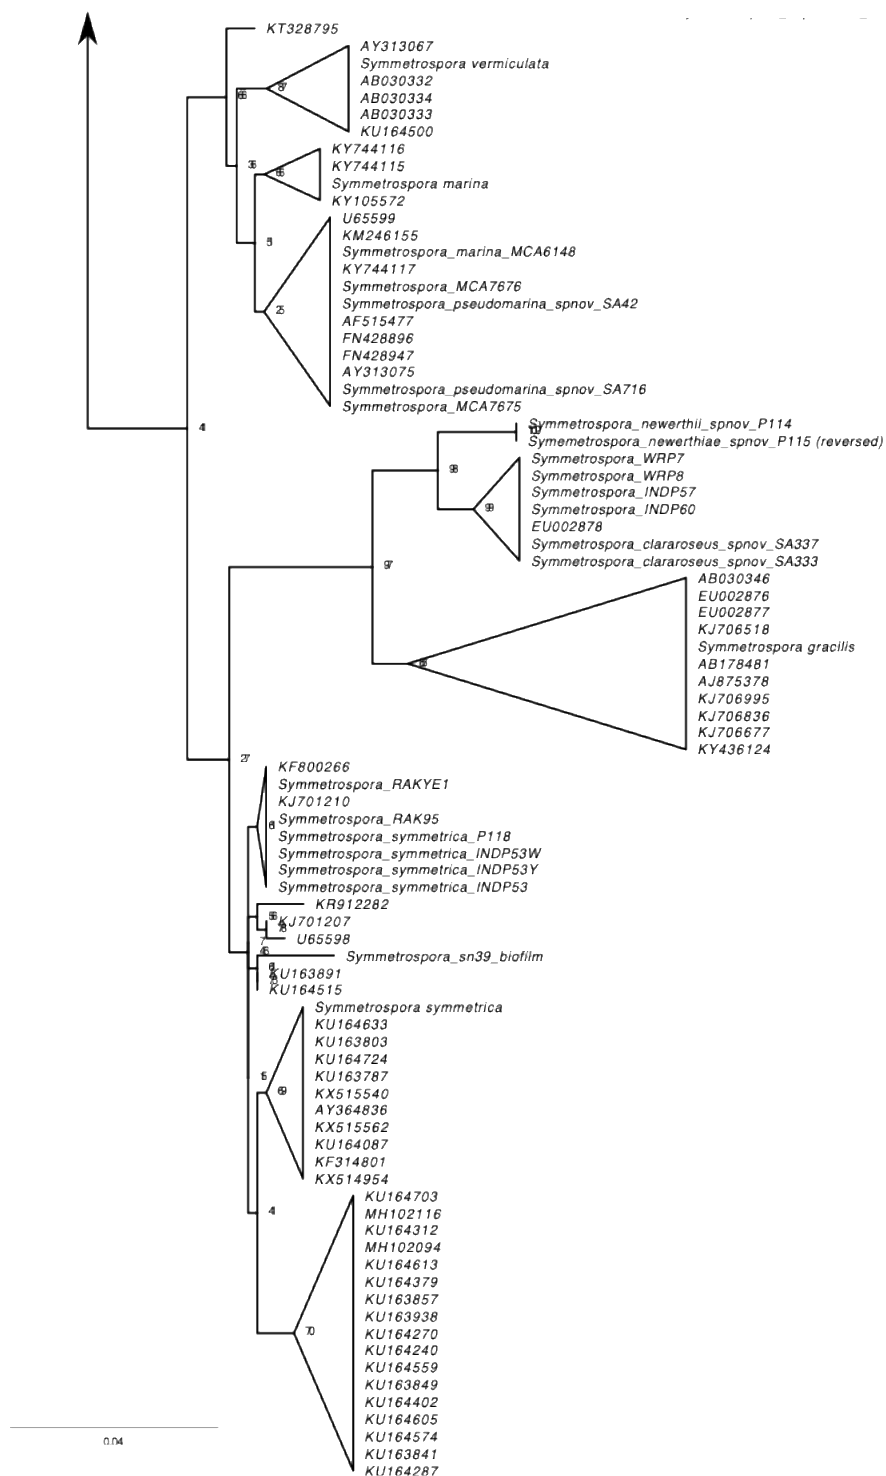

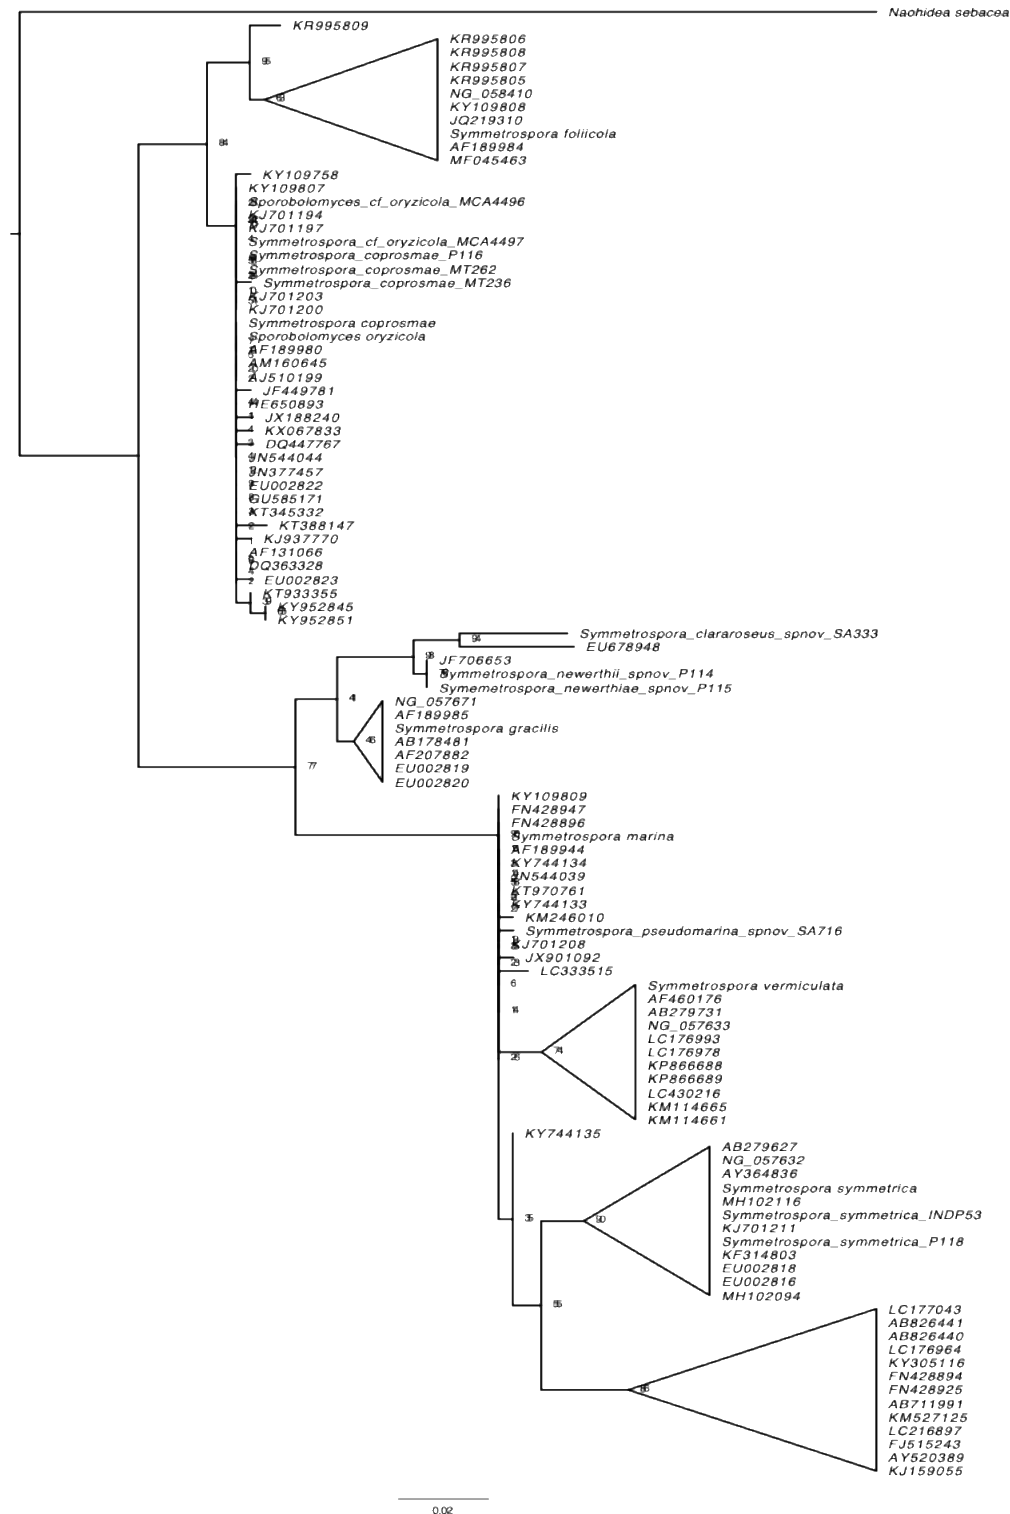

Figure A 12 Phylogenetic reconstruction of *Sakaguchia* inferred from the D1–D2 domains of nuclear 28S using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

Phylogenetic reconstruction of *Symmetrospora* inferred from ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

Continued Phylogenetic reconstruction of *Symmetrospora* inferred from ITS using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.

Phylogenetic reconstruction of *Symmetrospora* inferred from D1–D2 domains of nuclear 28S using ML. Bootstrap proportions are shown for each node. The tree is midpoint rooted and was used for species delimitation. Tree. Scale bar equals expected number of substitutions per site.
